If you don't have 2 dummy loads, there is a simple alternative. Connect the TX to the meter through a 1/4 wave section of 75 Ohm line. Unless the TX output was 75 Ohms, the equivalent TX output impedance seen by the meter has changed.

A critical point made in the quote below is evidence of a serious
misunderstanding concerning the relationship between the source impedance of the
tx and the load impedance.

>QUOTE: Output return loss is a measure of the interfering signal that is
>coupled into the output circuit versus the amount that is reflected back
>from the output circuit without interacting with the non-linear device. To

>the output source impedance of the transmitter is not fifty ohms. If the
>source impedance were equal to the fifty ohm line impedance, half of the
>transmitter's output power would be dissipated in its internal output source
>impedance.

The last sentence in the paragraph above is incorrect. This shows that the writer of the quote is in the unbelievably large group that still believes incorrectly that half of the tx power would be lost if if it were conjugately matched. But we all know that efficiencies greater than 80% is achieved by Class C amps, and greater than 60% is achieved by Class B amps when the source impedance of the tx is 50 ohms resistive and the load impedance is also 50 ohms resistive.

I have made appropriate measurements in a professional RF laboratory that prove this point. The data from these measurements and the procedure used is available for downloading from my web site at http://home.iag.net/~w2du under the title "On the Nature of the Source of Power in Class B and C Amplifiers." This piece is Chapter 19 in Reflections II, and also appears in QEX,, May/Jun 2001.

Unfortunately, like the statement made in the 'quote' above, there are all too many RF engineers who fail to appreciate the true relationship between the two separate resistances in the amp, the resistance resulting in dissipation and the resistance responsible for delivering the power to the load. I guarantee the reader of the piece referenced above will come away with something to think about.

|Just one sec, please. I didn't say that the true SWR connected to the tx
|output connector was affected. I said that the RF power measured at the
|sample point(s) in the transmitter can be affected by the source and load
|impedances of the tx, for the reasons stated.

Not so fast yourself. You said, "The generic function of this meter is
to measure the degree of match between a source and a load."

There is no power mentioned in your statement. I, and others, stated
that your first statement was incorrect and since that time you have
been introducing prodigious amounts of verbiage in an attempt to
obfuscate and avoid the obvious error in your earlier statement.

Just slap your forehead and say, "Shucks, I blew it with that one" and
we can all forget about it. I do it all of the time.

|
|The true load SWR does not change under these conditions, but it cannot then
|be determined by such a meter. Attempting to do so will yield some value,
|but it will be wrong.

Oh please. If an SWR meter, direction bridge, TLI or whatever you
want to call it has decent directivity, i.e. the ability to discern
forward and reflected power, forward and reflected waves, reflection
coefficient, scattering parameters, or whatever you want to call them,
then the applied power is immaterial.

We are trying to measure a RATIO, not some absolute value of power.

==========

It is at this point where impressionable novices are led astray by old wives, never again to return to logical thought on the subject.

They imagine that because the meter happens to indicate the swr on the line, the meter is actually responding to the swr on it. Whereas the meter is actually responding to the modulus of the reflection coefficient caused by the line's input impedance regardless of what its Zo may be. The act of making the line's Zo and the meter's resistance both equal to the transmitter's designed-for load resistance, has put additional infomation into the system. Cooking the books!

If there's an SWR to be indicated it is on a long line between meter and the transmitter. In the absence of such a line the meter wastefully discards half of the information it is presented with and indicates the modulus of the reflection cofficient. A more appropriate name is TLI.

> . . .

My NEC book is getting pretty old now, 1990, but at that time, multiple grounds were often not only permitted, but required. And a *minimum* spacing was sometimes specified.

For example, section 250-84, Resistance of Made Electrodes: "A single electrode consisting of a rod, pipe, or plate which does not have a resistance to ground of 25 ohms or less shall be augmented by one additional electrode of any of the types specified in Sections 250-81 or 250-83. Where multiple rod, pipe, or plate electrodes are installed to meet the requirements of this section, they shall be not less than 6 feet (1.83m) apart."

Or section 250-81(a), Metal Underground Water Pipe: ". . .A metal underground water pipe shall be supplemented by an additional electrode of a type specified in Section 250-81 or in Section 250-83. The supplemental electrode shall be permitted to be bonded to the grounding electrode conductor, the grounded service-entrance conductor, the grounded service raceway, any grounded sevice enclosure, or the interior metal water piping at any convenient point."

When I replaced the service (in 1979) in my 1952 house, the system ground was a water pipe connection and I was required to add a ground rod. Neither was considered adequate in itself; both were required by the code at that time.

I agree wholeheartedly about consulting an electrician. Non-electricians (including me) often have mistaken ideas about the content of the NEC. It doesn't hurt to have an up to date copy of the NEC for reference, either, if you anticipate doing any of the work yourself.

To Bill Turner,

my tests showed no difference between Horizontal and Vertical propagation. Vertical is quite busy here, lots of interference. Horizontal, on the other hand plays much better.

My question was antenna design, not the propagation issues. Thanks for trying though.

Maximum ground loss during wave reflection, between low resistance sea water and very high soil resistivities, could very well be when soil impedance is of the order of 377 ohms. Or is related to that number.

This is because, on the average of incidence angles, soil is more likely to absorb than reflect wave energy received from free-space. There's a better impedance match with free space at 377 ohms. The reflection coefficient is smaller.

Soil permittivity and frequency will also have an effect on the ballpark in which maximum absorption and hence maximum transmission loss lies.

>information other than the two voltage measurements is needed.

Hi All,

No mention merely means there is no offer of accuracy (not very
important, eh what?). These two measurements (repeated at intervals)
can reveal a SWR that varies along the length of the line like a snake
- UNLESS of course, you DO observe unmentionables like Load reflection
co-efficients and Source reflection co-efficients. As such, a
description of how not to measure SWR, but rather how to exhibit error
if you perchance have the misfortune of having a transmitter that is
unmatched to a 50 Ohm transmission system whose load is in fact
mismatched also.

Need I point out that if both ends are matched - what's the point in
measuring SWR? ;-)

Outdated only regarding water pipe Roy, but good advice. And Dave's above interpretation of NEC is a misunderstanding of the subject - easy to do so consult a professional if you have any douvbt whatsoever about what your are doing. Isolation transformers are not an option for isolating a station ground from AC service entrance. They are permitted only in lmited cases where independent grounding is required, and in other cases where HV isolating transformers or fiber optic isolate feedlines. No one in this group will likely have that requirement, so put that out of your mind Dave. You *MUST* bond your station ground to the AC service main ground. Ignore this at the peril of your entire system, which had better be 100% isolated from all power and external feedlines and grounds. That is an option for protection, isolating from *everything*. But it means unplugging and shorting to ground all feedlines, disconnecting and removing RF ground connections, disconnecting computer modems, telephone, and AC power to all of your connected equipment. A really poor option in my opinion, because if you forget something, or risk your life trying to disconnect during a surprise thunderstorm, what was it worth?

Hi Reggie,

Is THIS the soil in your garden? Must be miserable for DX! That would be an exceedingly deep pile of very dry sand you are on. Quite remarkable stuff where ever you might find it. Like the green cheese the moon was supposedly made of, you have more lore from the aged domestic goddess file than one could have imagined.

What coefficients would that be for your program? What would the conductance be? How many radials would it resolve to? Can you even guess the Q? So many questions and easily suitable for the Magic 8-ball "Try again later."

>or 250-83. Where multiple rod, pipe, or plate electrodes are installed
>to meet the requirements of this section, they shall be not less than 6
>(1.83m) apart."

Is it something like this? Multiple ground rods are permitted
(encouraged, even) in order to establish one good ground connection; but
the wiring system can have only one ground connection.

Would this help?

On the subject of whether the TX impedance affected the SWR reading, I
propose the following practical test:
Using standard CATV bits and pieces, connect up the following-
Signal source > directional coupler #1 > directional coupler #2 > load.
DC#1 picks off the forward signal, DC#2 picks off the reverse.
Use a spectrum analyser to measure signal levels.
Beforehand check the DCs for go directivity, and chose a frequency where
it is best (at least 25dB). This will probably be around 20MHz.
With good load, measure forward and reverse signals.
Repeat with known load mismatch.
Screw up source impedance (eg add T-piece at source o/p, and

double-terminate).
Repeat the above.
Think about what the results mean.

Ian.

>requirements and station layout.

Thanks very much for those thoughts, Jack.

As I'd guessed, you had some good suggestions, but you can see their practical problems too. The same applies to an alternative method, which is to group related items of equipment as closely as possible, and connect them by the shortest possible straps to a large sheet of metal.

The key feature is that this sheet should be *very wide*, to create a very low inductance and help minimize any voltage drops along its length. Conductor thickness doesn't matter in this location, so a sheet of copper-clad PC board is fine. It's also very easy to solder short grounding straps onto the PC board, and move them around without having to disconnect the whole sheet to drill it.

Some people put the sheet on the table, and the gear on top of the sheet. If there is a shelf carrying another level of equipment above, another practical way is to fasten the sheet to the underside of the shelf.

The reason why conductor thickness doesn't matter in this location is that we don't expect full-bore lightning surges through the station itself. The ground bonding at the common service entrance should have diverted the main surge safely to ground, so the equipment bonding inside the station should only need to deal with very much smaller currents - smaller, but still large enough to damage sensitive electronics. Also, the higher-frequency components of the surge will only run along the surface anyway, so what matters most is width and surface area rather than thickness of copper.

As Jack says, busbars are a particular invitation to develop voltage drops along their length. This "ground-sheet" system accepts there will be some voltage drop along its length, but does everything practicable

to minimize it. A wide sheet is vastly better than busbars, and solid copper busbars are a particular waste of money - a large sheet of scrap PC board will do it far better, for almost nothing.

If I had the luxury of a large station, I'd use these sheets as part of a wider-scale "grouping" system, as Jack suggests.

>Just realize that in a nearby-by strike, lightning will find the weak
>points in any system and exploit that weakness to the fullest
>possibility.

In this climate, lightning is actually quite a minor hazard. What has driven me to organize and bond equipment together is the need to control RFI due to ground currents (of which I generate rather a lot). What's good for the one is generally good for the other... and often good for received noise reduction too.

Good Morning Andrey,

What you are proposing is not an easy task any horizontal antenna placed close to a good ground plain is going to have most of it's signal at 90 degrees. (Straight up) Until the antenna is at least 1/2 wave above the ground plan. at that point it will start to show radiation to the horizon. EZNEC shows max gain at 30 degrees to the horizon for a 1/2 wave horizontal dipole mounted 1/2 wave above perfect ground and the pattern looks somewhat like a peanut shape. if you move the antenna up to 1 fullwave length above the ground plain then the patern does not change much but the elevation angle dose you then get a good lobe at 15 degrees and another at 45 degrees. hope this is of some help.

Well, yes and no. As I read it, all the ground electrodes have to be connected to the service box, as they are at my house. I have a water-pipe ground and a ground rod; they're physically widely separated, and each has its own conductor going back to the service box. So I guess you could call the service box a single "ground connection". The neutral and safety ground conductors of each circuit are individually grounded at the service box also, giving further support to interpreting its function as a single ground connection. A number of ground methods and devices are approved, such as buried rods or plates, concrete grounds, or (in my old code book anyway), water pipe ground. Some can be used alone and others need a second ground device as a supplement. When multiple ground rods are used, the code has requirements for bonding them to each other.

2833. Re: SWR meter vs TLI

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-05 10:14:46 UTC
From: richardharrison@webtv.net
Message-ID: <926-413AE716-16@storefull-3258.bay.webtv.net>
Source record: 89955

Richard Fry quoted Geoffrey Mendenhall who is responsible for the entire Harris broadcast transmitter line design as saying:
"If the source impedance were equal to the 50 ohm line impedance, half the transmitter`s output would be dissipated in its internal output source impedance."

Mendenhall is wrong.

A Class C amplifier`s "internal output source impedance" is largely "dissipationless resistance" produced by the non-conduction time during its RF cycle. A matched Class C amplifier typically produces efficiencies exceeding 50% by a comfortable margin. That`s why they are used despite their harmonic generating nonlinearity.

Best regards, Richard Harrison, KB5WZI

However an SWR meter, direction(al) bridge, TLI or whatever you want to call it has NO ability to discern between two waves traveling in the same direction, unless their detectors are operating in the time domain -- which normally they do not. That is the "feature" causing the anomalies I have been writing about.

Richard Fry wrote:
"It doesn`t matter whether we state the result of measurement in units of SWR, return loss, or as a reflection coefficient -- they all give the same information -- ."

Correct. The units above are fungible. All are an expression of the mismatch of a load to the Zo of the transmission line.

With a Bird wattmeter, the reflection coefficient (rho) is the sq. rt. of the reflected power divided by the forward power.

SWR = 1+rho / 1-rho

Return loss in dB = 20 log (rho)

Return loss in dB = 10 log (Ref.Pwr./Fwd.Pwr.)

Rho = (ZL/Zo)-1 / (ZL/Zo)+1

None of the expressions above include the source Z, therefore it does not apply.

> What, then, is "system SWR"? How do you define it?

System SWR is the net SWR of a component assembly present at its input terminals. "Antenna system SWR" then is comprised of the net SWR of everything in the RF path from the output of the SWR meter to and including the antenna. In a transmitter, the antenna system begins electrically at the output of the SWR meter -- physically close to the output connector of the tx.

> Obviously, if we have a voltage or current source of fixed value
> and change the source impedance, the power delivered by the
> source changes,

But the mechanism I've described considers the re-reflection by a mismatched source of power not initially absorbed by a mismatched load -- not that a change of source impedance changed the total power flowing out of the source.

> ...both the "forward" and "reverse" powers
> will change, but by the same fraction...

Agree. I'm not so sure that the Model 43 or equivalent methods used in/with transmitters accurately preserves the power ratios under these conditions, though.

He he he.

What if your garden is in the 'near field' ? (Obviously no "what if" at all - it almost certainly is.) Then the garden should be some other value, NOT 377 ohms, to match your locally generated EM wave.

Also, the ground properties would obviously be NON RECIPROCAL (!!!) since the other guy's signal would presumably be in the far field and would arrive in the V/I ratio of 377 ohms.

What's a directional coupler?
What do they look like?
Don't bother answering those questions.

Why do the arguers, when caught in a tight corner, always escape to UHF for help from directional couplers?

There are NO directional couplers at HF. They are as scarce as real swr meters. So they cannot be used in futile attempts to explain what really happens at HF.

You're next move will be to drag in scattering-matrices.

So what is the element in my Bird Thruline then, and how does it work?

I'd dying to hear at what frequencies directional couplers suddenly begin to
"exist". A sudden change in the laws of Physics at some arbitary frequency
named by man.

(Most SWR meters I've seen use a directional coupler, by the way. Even the
cheap ones.)

I think we've got to the root of Reg's problem. Just like the last time he
raised this nonsense.

To Walter Maxwell:

1. You may be interested in reading Mendenhall's complete paper, which I will email to you. The lab measurements reported in it used two, operating, high-power FM broadcast transmitters -- and support his statements about amplifier source impedance and its consequences.

2. I will ask again, if transmitters have a 50 ohm source impedance, what accounts for the fact that TV ghosts are produced by an antenna system reflection having a sufficient delay time? Calculations and measured data show that the energy that produced the ghost originated by re-reflection off the TV transmitter output stage of far-end reflections in the antenna system. If the tx source impedance was 50 ohms, it would absorb the far-end reflection, which would be incapable of producing a ghost image.

Further, if the tx source impedance was 50 ohms, then the RF intermodulation measured and reported in Mendenhall's paper -- and verified in real-world installations by the radiated interference those IM products produced -- would not occur.

Reg, I thought that a DC was essentially any device which sampled some
of the RF signal travelling in one direction, and (if perfect) none of
the signal travelling in the other. Over the past 40 years, I have had
lots of dealings with them. I've even designed some which were bought in
their thousands (if not millions). Some of them seemed to work from
below 5MHz to over 870MHz (well, I THOUGHT they did, and so did the
people who bought them).

Where did I go wrong?

On the positive side, I never went as far as to claim that they would
measure SWR.

Ian.

By strapping the coax to the earth,ground or negative (or whatever) part of the aerial,you will effectively
cancel out any gain or effect the 20' part had.
Obviously you dont have the space for a 'T' where the coax is the bottom bit of the 'T' and the top
Parts are say 20' each way give ot take?
If thats no good,then how about feeding the coax to a longer wire closer to the house and having
the ground wire going down to earth,vertically? If you could have the long wire inclining up the
garden somewhat,it would be effectively an inverted-v antenna.Keeping it horozontal would
leseen the tendancy to throw signals back over your house however.
Does this help?

|Why do the arguers, when caught in a tight corner, always escape to UHF for
|help from directional couplers?
|
|There are NO directional couplers at HF. They are as scarce as real swr
|meters. So they cannot be used in futile attempts to explain what really
|happens at HF.
|
|You're next move will be to drag in scattering-matrices.

Why not. I have used an HP3577 network analyzer with an S-parameter
test set that was specified to work over the frequency range of 100 Hz
to 200 Mhz.

I guess the guys at HP didn't realize that you can't do this.

And another example in point:

From the input to a TV transmit antenna system, tx disconnected, I have personally measured the far-end antenna system reflections of a 2T sin² video pulse (0.25 µs H.A.D.) modulated onto a TV channel carrier, and detected by a vestigial sideband demodulator tuned to that TV channel. A high-directivity directional coupler at the input to the main line, a display device, calibrated attenuators, and the time difference between the incident and reflected pulse enable accurate measurement of the reflection coefficient of the antenna system.

This was a common practice after a new antenna system installation to measure and optimize the far-end match for the best quality radiated signal, and was pioneered by RCA Broadcast Eqpt Div, my employer at the time. More elegant means are used these days.

When this test shows a 5% pulse return 2 µs after the incident pulse time (for example), then the same pulse passed through the tx also shows nearly exactly the same reflection % and time separation -- assuming there is enough RF delay in the system for the reflection to be resolved in the demodulated waveform.

As the directional coupler driving the normal demodulator at the TV station is looking at forward power only, it is clear that the reflection from the far end of the antenna system has been re-reflected from the TV tx output stage, and NOT absorbed by it in its "conjugate impedance."

Hi Richard,

But this gets curiouser and curiouser (as Alice through the Looking Glass would offer).

Cited as an example of the "NOT 50 Ohm" society (and one of its leading proponents) we find that Geoff Mendenhall's notable achievement in 1968 was building a 400W FM amplifier. Truly a hands-on achievement. Now if we simply review the historical archive and ask Geoff himself what the Z of his design was, we find by his own hand:
RF Output Impedance: 50 Ohms

Let's see, no technical argument, and sources that are self-contradicting. Whatchagonnado? Punt? :-)

OK. Earlier you wrote, "To date in this matter, I have yet to see any concrete value of source Z offered from those of the NOT 50 Ohms camp. Further, I have yet to see any of them offer any experimental confirmation of their assertion (made rather simple by the exhibition of uncertainty)."

Our controversy is illustrated by my posts with an opposite conclusion, beginning last night and continuing this morning.

As for experimental evidence, I report some in my post here of a few minutes ago about making refl coeff measurements of TV transmit antenna systems.

Mendenhall's paper also has experimental evidence of this. I will email it to you.

I trust my contention is now clear to you.

Hi OM,

Actually no. Your reference, Mendenhall, specifically writes about
his design:
"It was necessary to determine the plate
load impedance (formula) = 1000 Ohms
where Emin min drop across the tube in saturation
I1 ac plate current.

"Since this Zp was to be coupled into a
Z output of 50 Ohm, a impedance transformation
of 20:1 was needed."

Fairly straightforward stuff there. Geoff's own notes are the model
of economy and directly to the nut of the issue. His notes are also
straight from old school first principles. As often happens, the more
elaborate the discussion of rather simple matters belies the inference
of hucksterism.

Seems like ALL my arguments, references, citations, data offered and
so on are congruent with Geoff's own description of amplifiers. I
certainly need no further testimony from him as I am perfectly capable
of finding his own work and offering it here. Thanx anyway, but no
thanx.

It would also serve you better to read more and write less, after all
I SPECIFICALLY mandated a discussion of transistor amateur amplifiers.
When I allowed this divergence to tubes, Mendenhall himself proved
that NOTHING changes in the physics of sources.

You assume he refers to the source impedance of/at output of the amplifier. More likely he is following convention and stating the load impedance that the amplifier was designed to work into.

The source impedance of most transmitters is not published even today. If it was, probably we wouldn't be having all of this confusion about it, and its effects.

It isn`t sudden.

They sure work at audio frequencies. In telephones, they are used to
prevent the user`s voice from overpowering the distant party`s voice in
the user`s ear. They are called hybrids.

Hybrids are also used to couple a 2-wire circuit which simultaneously
carries both directions of transmission with a 4-wire circuit consisting
of a transmit pair and a receive pair.

At least there appears to be an acknowledgement that some RF amplifiers do not have a source impedance that is the conjugate of their load impedance. So progress has been made.

>Actually no. Your reference, Mendenhall, specifically writes about
>his design:

Hi All,

I would add further, Mendenhall's notes of his design, as the model of clarity, include references, one of which is particularly notable and estimable within this group:
"Treman [sic], F.E.; "Electronic and Radio Engineering";
Mc Graw - Hill Book Co.; 1955"
the same publication I've had since the same date that Geoff built his transmitter. Geoff's attachments also include the data sheets from Eimac which show quite plainly that ALL of his formulas and computations are congruent with ALL sources of information in his references.

Another reference:
"Goodman, Byron (Ed.); 'The Radio Amateur's Handbook';
American Radio Relay League; Newton, Conn.;
1966"
(I used to have that publication, back then, too)

I also vaguely note some inference of peculiar intermodulation products that would be produced by a transmitter with 50 Ohm output characteristic - in that I may be mistaken because when the verbiage gets particularly dense to explain simple matters, I must admit my own filters kick in. However, Mendenhall's work was not simply that of an amateur's project, nor was it a school term paper, nor was it the speculation of an engineering sales pitch.

The report I am drawing upon was Geoff's own Type Acceptance application to the FCC which included all the technical specifications of spurs, intermodulation products, stability, efficiency (80%), class of operation, modulation, out-of-band responses.... I don't think I need go much further. :-)

For those who wish to read the COMPLETE story of how to build a rig,
how to specify it, how to measure it, and to note how it exactly
conforms to conventional wisdom; then visit:
http://www.techatl.com/wrek/docs/gnm_0011.htm
where you will find all of one page of theory, and 40 odd pages of
reality:
The WREK 425 Watt RF power amplifier, also known as the
"Goat-Mitter" was designed by Geoffrey N. Mendenhall (dubbed the
Goatman by WREK announcer, Ed Esserman) and constructed entirely
with hand tools by Geoff and the WREK staff in August of 1968.

Thank you Dave,

for sharing with me results of your simulation. I got similar results. The thing that works is slit pipe (Alford's slot, see http://www.eta.chalmers.se/~pgp/alford_slot/alford_eng.html for example)

Pipe works over ground plane as well (not as well, beam gets lifted, stll there is enough energy looking on the horizon). It is such a cumbersome thing though - looks funny on car's roof. Not of ractical use.

And I still can not find anything else that does it.

Regards,

Andrey Gleener

Those may be anomalous. I recommend King, Mimno, and Wing to anyone desiring the complete story on the conjugate matches.

To the extent that the amplifier is designed for a performance on demand that stresses it to its maximum safe dissipation, an amplifier of the Class C variety is designed for a perfectly matched load. It`s the economical thing to do.

You supply the tube with about all the volts it can safely take. Then you supply it with just enough load impedance to limit its current to all it can take under the heaviest loading it well encounter. That would be when it is conjugately matched to a 50-ohm load, the usual cable impedance specification.

The tank circuit is mostly a harmonic filter providing a very high impedance to the fundamental frequency and shorting out the harmonics.

Source record: 89886

(Jumping in after this argument has gone on for a long time)

This has evolved somewhat into an "apples and oranges" discussion. What Richard Fry appears to be concerned with is the reflection of a video pulse by the load (antenna) and its re-reflection (at a later time, dependent on the length and Vp of the transmission line) by the source (transmitter) and subsequent radiation (as a ghost image--the effect repeats, ad infinitum).

While this is certainly a real phenomenon, its effect is a function of both the mismatch at the load (S11) and the mismatch looking from the transmission line back toward the source (S22). It does NOT influence the VSWR and could, obviously, be significantly reduced by the use of a circulator at either end of the transmission line (which may not be practical at the power levels of televison transmitters, to use his example.)

First transmitting plant I worked in back in 1949 was that of KPRC / KXYZ. These each used an RCA 5-C. Transmitters were 250-watt exciters driving 5 KW water cooled linear final amplifiers. The interesting thing about this plant was that the 950 KHz and 1320 KHz transmitters both fed a common main antenna. Each station had its own directional tower on the side.

The way to avoid intermodulation is to keep the foreign signals out of the electronics so they don`t mix. Well designed and adjusted pass/reject fikters in the transmission circuits of KPRC and KXYZ saw to that.

==========

Wes,

Why do USA citizens invariably introduce the type numbers of their
favourite, indeed worshipped articles when they have not the slightest
bearing on an argument. To base one's position on a lifeless piece of
hardware rather than logic is surely unsafe.

What on Earth is an HP3577? In the whole of my career I have never heard of
the number 3577. Is it a prime? Traditionally, in the UK, the letters HP
on the side of a savoury sauce bottle stand for "Houses of Parliament".

Unless a 3577 can unambiguously measure the swr on a non-existent
transmission line I'm afraid its presence will serve only to further
agravate the argument. Which I'm sure is the last thing you would want. ;o)

Can it?

I wasn't talking about skip either- the majority of V/U weak signal work is
extended ground wave via perhaps enhanced tropo.

1.Horizontal polarity can take advantage of ground gain reflection that
vertical polarity cannot.

2. In addition, at 900 MHz where a wavelength is just over a foot, even
mounting the antenna at 12" would place the first lobe at 15 degrees,
assuming the car roof completely determines this- and I doubt that it has
much of an effect on far field take off angle.

Incorrect. See my post earlier today about reflection measurements I made of TV transmit antenna systems. That's better than the bench. It's real life. The thesis has been proven.

> Even in the comedic foray you are seriously mismatched.

An arena in which I don't (and don't wish to) compete, however.

Gentlemen, excuse me butting in.

I suspect all these learned articles to be invalid because the authors incorrectly assume the source impedance to be constant and the load impedance to be the variable in any analyses or sets of measurements.

Whereas the internal or source impedance is actually a function of the load (and many other factors).

I have not read these papers or articles but base my comments on what I have gleaned from newsgroup conversations over the years.

In brief, how can you have a conjugate match with the source impedance hopping about trying to follow the load? ;o)

Thanks. You report more evidence that the source impedance did not match the load impedance of these txs. If they did, each of these txs would absorb the coupled signal of the other -- and neither of them would generate mixing products.

A mistake?

Sorry if I misquoted Richard Fry on peculair intermodulation products.

The power hungry RCA 5 C`s with their linear amplifiers were later replaced with RCA BTA5F`s which had Class C final amplifiers. Despite a phony ceremonial switchover to the new equipment in which pads were pulled from the audio lines to the new transmitters, the stations really sounded the same before and after the equipment change.

Thank you Rick, I've received the Mendenhall paper, which I'll review and
comment later. However, before reading it I have one comment. On the condition
that the tx has tubes (and I assume it does) with some sort of LC output
coupling network, then if the source impedance of the tx is 50 ohms it will not
absorb the far-end reflection, because the source impedance of this type of tx
is not absortive. The source impedance of a resonant tank circuit is a
resistance determined by the voltage-current ratio in the tank--high resistance
at the tank input and low resistance at the output. The resistance being
proportional to the load line there is no dissipating resistor involved. The

only dissipative resistance in the system is the cathode-plate resistance, which is separate from the output resistance. And contrary to what I've skimmed in the Mendenhall paper, the output circuit of the tx is linear, not non-linear as Mendenhall says, because the energy storage of the tank isolates the non-linear input from the linear output. Remember, the tx output is a nearly perfect sine wave.

I'll not comment further on this point, Rich, until I've reviewed the Mendenhall paper.

Why would they? One is tuned to 950 KHz, the other to 1320 KHz, a
good part of an octave difference.

This is the same fuzzy logic that says that you can measure the output
Z of an amplifier at one frequency by injecting another signal at a
different frequency.

If it was this easy, the bother of load pull techniques wouldn't have
become popular and the norm.

You've still lost me. Let's say the "component assembly" is a half wavelength of 75 ohm transmission line terminated with a 75 ohm resistor. What is its "net SWR"? How about a half wavelength of 75 ohm line terminated with 50 ohms? Or a plain 75 ohm resistor? You surely have an equation you use to calculate "system SWR" or "net SWR" -- can you share it with us?

This is getting more complicated rather than simpler. We now have "true SWR", "antenna system SWR", and "net SWR". Quite a step from the ratio of maximum to minimum voltages on a transmission line.

To shed more light on this, when I tried to find information in the literature about transmitter output impedance, I ran across two cases where reflections from the transmitter are bad. One was the case of multiple transmitting antennas on one tower; a particular antenna could pick up another transmitter, and then re radiate it with some delay. The second was the case of a wide band spread spectrum transmitter, where it is not possible to have a good antenna match on all frequencies.

Gotta' disagree here, Richard, conjugate matching a Class C tube amp doesn't require the heaviest loading it will encounter. A conjugate match can be obtained with any loading you choose. For example, you can set the drive that will permit loading to any particular level of maximum output power into any load within the tank circuit's available matching range. So let's assume you set the drive to provide a max output of 100 w into a 50-ohm load by adjusting the tank controls for maximum output. The source resistance is now 50-ohms, there is a conjugate match, and the amplifier has not been loaded to the heaviest loading it will encounter. In addition, if the load was 70 ohms and the tank adjusted for maximum output, the source resistance would now be 70 ohms, and there'd also be a conjugate match.

If you question my statements above see the data from my measurements using professional grade instruments in either QEX, May/Jun 2001, Chapter 19 in Reflections II, or from my web page at http://home.iag.net/~w2du.

Hi All,

It doesn't take much research into the matter of matching and Harris
Transmitters to find from their Digital AM stations:

The newest Harris AM Transmitters of 10 KW and higher (up to 1
megawatt and more) are totally solid state and use a completely
different modulation system called Digital AM Modulation. This
scheme is another Harris Patented system, using a large quantity
of plug-in modules, each one generates RF at a different
modulation level; in order for this to function, any incoming
audio (if analog) is broken down into digitized data, then used to
drive the various modules at the varying levels needed to have an
amplitude modulated output. It sounds pretty simple, in fact,
each module has a torroid (coil) which is the load for that
module; all those torroids are lined up and an iron pipe is run
through these torroids so that the combined output of all the
modules is coupled into this pipe. One end of the pipe is at
ground, the other end is the RF output of the transmitter. There
is an output network to match impedance of the pipe, which is
probably only a few Ohms, to the required output impedance which
is usually 50 Ohms, although sometimes high power transmitters are
set up to provide 75 Ohms, once in a while even 300 Ohms, to drive
an open wire type transmission line system.

Hardly a wit difference between Geoff's first FM amplifier design that
was documented for FCC type acceptance and now when it comes to
matching - all very commonplace and not even a hair out of place in
the conventional wisdom found in Terman (one of his references).

As for the specification for output impedance gone missing :-)
MW-10B SPECIFICATIONS
RF OUTPUT IMPEDANCE: 50 ohms, unbalanced.
Other output impedances available on special order.

Harris Platinum Z FM transmitter
100 ohm output impedance (unbalanced)

HARRIS SW-50 A
RF Output Impedance 300 ohms balanced, 2.0 to 1 maximum VSWR

Well, instead of reciting their complete catalogue, it is easier to simply say I could not find any product that did not specify an output impedance, much less that others were available on special order.

One wonders if it doesn't matter, do they just change the spec page and the sticker above the connector? ;-)

Rich, I've got to tell you that you've just proved that the output circuitry of the tx doesn't absorb the reflection from the antenna, but instead, re-reflects it, because the output source resistance is not dissipative, only the cathode to plate resistance is dissipative.

And the output source resistance is not dissipative or absorptive if the impedance match is 'conjugate'. Contrary to what Mendenhall said that the tx would absorb half the power if the source resistance is 50 ohms, there is nothing special about the conjugate relationship that would produce this effect. The tx will re-reflect whatever the match relationship is between the tx and its load.

Hi Rich, it's interesting that you were on Geoff's staff. On the paper you sent me, the location of the company appears as Quincy, IL. When I bought the tx for new BC stn WCEN in 1948 it was from Gates Radio in Quincy. Is it possible that Geoff's business is a spinoff from Gates?

It's also interesting that you were also with RCA BC Div. I was with the RCA Labs in Princeton, and working with me in the same lab room in 1960 was Don Peterson, who was running an experiment suggested by Dr. George Brown. The experiment was in developing the use of TDR for finding discontinuities in RF feed lines for TV. With the success of his experiments we could pinpoint the location of a discontinuity that produced a reflection causing no greater than 1.03 SWR. He developed a kit for use in the field for locating ghost problems in the lines connecting the tx to the antenna. Were you aware of Don's work in this area?

|bearing on an argument. To base one's position on a lifeless piece of
|hardware rather than logic is surely unsafe.

Well, I cannot speak for all US citizens and *invariably* is a little
too all encompassing for me. But I suppose it's similar to declaring
so unequivocally and "logically" that there are NO directional
couplers at HF. When presented with a real-life instrument that
includes these non-existant couplers that you refer to, you wish to
attack and belittle the presenter.

If you don't know what an HP 3577 is, you might ask in a civil manner,
in which case I would say that it is a vector network analyzer,
covering the frequency range of 5 Hz to 200 MHz that was widely used
in this country as well as around the world.

An accessory to the instrument is an S-parameter test set that offered
the ability to measure full two-port parameters over the frequency
range of 100 Hz to 200 MHz, which last time I checked, includes the hf
spectrum.

|What on Earth is an HP3577?

See above.

|In the whole of my career I have never heard of
|the number 3577.

Clearly, you have lived a sheltered professional life.

|Is it a prime? Traditionally, in the UK, the letters HP
|on the side of a savoury sauce bottle stand for "Houses of Parliament"

Perhaps, but me thinks that the sauce that you are more familiar with
says something different.
|
|Unless a 3577 can unambiguously measure the swr on a non-existent
|transmission line I'm afraid its presence will serve only to further
|agravate the argument.

Surprising to you perhaps, yes it can.

Reg, I have a myriad of measurements which prove that when the pi-network is adjusted to deliver max power for any reasonable drive level into any reasonable value of load, the source impedance is the conjugate of the load impedance. When adjusting the load control of the network for max output the output resistance equals the resistance of the load. And when the plate tuning is adjusted for max out the reactance injected into the network equals the reactance opposite to that in the load. To be practical, be assurred that the tuning and loading controls are alternately adjusted continuously until they converge and the max power is delivered.

Having performed these measurements many, many times, I assure you that the resulting data isn't a series of coincidences. So instead of the source impedance 'hopping about trying to follow the load', when the network is correctly adjusted, the source impedance 'finds' the load and stays put until the load is changed and the network readjusted to accomodate the new load.

To Rich Fry,

Rich, I just now saw Richard Clark's post above. Until reading it I was totally unaware that high-power BC transmitters used solid-state final amps.

Consequently, my comments were all directed toward tx's using tubes and LC networks to isolate the non-linear input from the linear output. I'm not at all familiar with the circuitryused in solid-state amps, please interpret my comments accordingly.

And Reg, in conjunction with the HP-8405 Vector Voltmeter, the HP-778D dual directional coupler can measure SWR from 1 MHz to 1 GHz with no transmission line whatever. This combination is the workhorse of my RF Lab.

I sense there's still a failure to communicate.

If Dale means by "V/U" VHF and UHF, ground wave isn't a viable means of propagation anyway. The attenuation of ground waves increases with frequency, to the point that they're virtually useless at VHF and above. So at those frequencies, I'd think the polarization choice for short range communication would be based on how it affects attenuation, multipath, and QRM. Given those criteria, horizontal might well have an advantage for short range communication, in some locations at least. And it's long been favored for long range VHF/UHF communication.

Ground wave? Really? I admit I'm not a propagation expert, so I'd appreciate an explanation from someone who is. Is there really enough ground wave propagation at VHF/UHF to be useful for any purpose, even short range communication?

You'd get that 15 degree lobe only if the roof extends far enough from the antenna to reflect a wave going out at an angle 15 degrees below the horizon (plus a bit, because the reflection doesn't actually take place from a single point). At 12" above the car roof, the 15 degree downward wave strikes the roof 12/tan(15 deg.) ~ 45 inches from the point below the antenna. So the the car roof would have to extend at least about 4 feet beyond the antenna in the direction you're sending in order to get that 15 degree lobe with the antenna 12" above the roof.

Have you tried an halo or loop antenna? M2 Antenna's and Par Electronics makes them. Homebrew plans are on the net.

The halo is a 1/2 wave dipole bent into a circle. Common designs use 1 turn, but 3 turn halo's have been used, with more gain. Stacking 2 halo's also provide additional gain. Weak signal operaters on VHF and UHF use them mobile on a regular basis.

No, it isn't ground wave at all. It's just a loose way of saying "normal short-range VHF/UHF propagation" which is a complex combination of line-of-sight, diffraction and scattering.

At medium ranges - which can be several hundred miles between well-equipped stations - atmospheric refraction and scattering are the main mechanisms. When weather systems lead to an "opening", signal strengths and workable ranges are enhanced by much stronger refraction and ducting.

Hi Walter,

In MY kitchen I have two workhorses, comprising the -

Autek Research, RF Analyst, Model RF-1, Frequency range 1.1 - 36 Mhz

and the -

MFJ, HF/VHF SWR Analyser Model 259-B, Frequency range 1.8 - 170 MHz.

Both were made in the USA. I bought the 2nd one in the hope it might be
better than the first. It wasn't. Nevertheless, between them they are the
best things since sliced bread.

The last measurements made using them were of soil impedance vs frequency,
in the kitchen sink, on samples from my backyard.

And the accuracy of any instrument depends on how it is used rather than on
what the manufacturer says about it.

"Is it possible that Geoff`s business is a spinoff grom Gates?"

Harris Intertype Corporation, predecessor of Harris Electronics, axquired Quincy, IL`s Gates Radio in the 1950`s, I believe. Then Harris really hit the acquisition trail. It acquired R.F. Communications, a 2-way radio manufacturer. It also acquired a telephone and SCADA equipment manufacturer, which had a government equipment and semiconductor division in Florida. It acquired Farinon Electric a microwave manufacturer in California. There were other acquisitions, Lanier which made office equipment such as duplicators. It acquired a hardware manufacturer which made 19-inch equipment racks among its products. I don`t about other shuffles in Harris` portfolio of companies, but the companies it bought were among the best at what they did at the time of acquisition.

Walt, forgive me for stating the obvious, but when operating under
non-linear conditions, as tubes and transistors are, I think you'll agree
that when the load resistance is changed, the tubes operating conditions
also change, and so does the tube's internal resistance.

I don't know exactly how you have conducted your measurements. But I suggest
that when you change the load you automatically force the internal
resistance to change with it.

But in any case, whichever way the source changes, the basic idea of a
conjugate match to an unstable source is itself not very sound.

The best way of determining source impedance is to mathematically model and calculate it. It need not be accurate. It is necessary only to show that it does change.

The accuracy of measurements depends on who uses the instruments rather than on what the manufacturer says in his sales catalogue. I'd much prefer just to take your word for it, Walt. The manufacturer's type number is superfluous - it sounds like a gratuitous advert.

When I was a lad, I learned that the 'goundwave' requires the flow of current in the ground, and is intimately tied up with the ground conductivity. Its attenuation rises rapidly as frequency increases, so is essentially only a low-frequency phenomenon. It requires a vertical antenna.

Propagation at the higher frequencies is via 'spacewave', which has nothing to do with currents flowing in the ground.

Many years ago, there were lots of discussions about whether vertical or horizontal polarisation went further. In the UK, many of the (no longer used) VHF TV transmitters used vertical. I don't think that the US ever used vertical for TV. I think that the verdict eventually was that horizontal won by a very short head.

At UHF, horizontal is invariably used for the high power TV transmitters, and the low-power fill-ins nearly always use vertical. There is therefore little opportunity to make a practical comparison of which polarisation is consistently received at great distances - it's always horizontal.

As for short range mobile and portable communications, propagation relies so much on 'bouncing off things' that it probably doesn't matter. Circular is probably best, but vertical physically easier. I can't imagine why anyone would want to use horizontal.

Cheers,
Ian.

Walter, W2DU wrote:
"A conjugate match can be obtained for any loading you choose."

No doubt. A conjugate match permits maximum power transfer. No other load can extract as much output as a conjugate match. Were I designing a broadcast transmitter for a 50-ohm or a 75-ohm load, I would want my money`s worth from the output devices I`ve selscted, consistent with a long useful duration.

I`d design for a conjugate match at the rated load and include overload protection for an output short circuit or near short. For solid-state I`d provide overvoltage protection.in addition to overcurrent protection.

Harris solid-state medium wave transmitters have a number of amplifiers supplying the output and a faulty amplifier can be easily removed from service while the remainder continue operation almost as if nothing had happened, if I read their internet pages correctly.

"---when the load resistance is changed, the tube`s operating conditions also change, and so does the tube`s internal resistance."

I would think that change in operating conditions result from readjustment of the amplifier, not from changing the load on it.

Most of the output impedance of a Class C power amplifier tube does not come from the saturation resistance when switched on, but comes from the duration of the period in which it is switched off. Until you readjust drive, the on and off periods and even the saturation resistance of the tube remain unchanged.

I won't try to soften this: your conclusion above doesn't just _appear_ to be wrong, it IS wrong. 100% wrong. The impedance published by Harris is the expected load impedance, not the tx source impedance -- which is the convention used by all OEMs of broadcast txs (at least).

How do I know? I was the author of all of the brochures and technical data sheets for Harris' entire FM product line for the ten years before I retired. That any published value of impedance applied to the load impedance expected was/is universal across the product lines: AM/FM/TV.

Your post above showing 100 ohms for a Platinum Z FM tx also is wrong. It is designed for a 50 ohm load. Here is a link to an on-line brochure for the current 10kW model:
http://www.broadcast.harris.com/product_portfolio/prod_media/HAR173569.pdf
Observe the statement at the bottom of the right column on the last page thereof, which I quote below for your convenience:

"All specifications referenced to any single output frequency
(87.5-108MHz),
nominal rated output power, and 50 ohm, isolated, non-reactive load."

No other RF impedance spec is given in the very detailed list of specs contained in these brochures.

Kindly recant your accusations.

Yes, Harris-Intertype (later just "Harris Corp") bought Gates Radio, lock, stock and barrel -- not a spinoff.

Vaguely. My primary contact and mentor was Dr Matti Siukola, lead engineer at RCA's antenna lab and test range at Gibbsboro, NJ. Under his direction I was responsible for updating and improving the VHF and UHF RF pulse test sets used by RCA Field Service.

I use a horizontal omnidirectional antenna for 2M in the truck while working SSB. Most home-based 2M SSB stations run horizontal polarization (at least here in the USA). I use it to help avoid the 20 dB or so loss that occurs from crossed polarization.

Same here in the UK. However, SSB is generally associated with longer
distance working (for lots of reasons), and folks tend to have larger
antennas then for local ragchews on FM (often through a repeater). If
you have a large antenna, it's physically easier to make it horizontal
(eg fewer problems with mounting it and avoiding the mast). If you
regularly work the SSB guys, you would certainly want to use horizontal
when mobile, especially as SSB is much less forgiving than FM is to the
deep and rapid flutter that is accentuated by cross-polarisation.
However, I think it's not so much a case of 'wanting' to use horizontal,
it's more like 'having' to.

Hi Richard,
I don't have anything to do with broadcasting, but when I first ran across their DX line of AM transmitters, it really blew my mind. It seems though, that it is really hard to find detailed info on them. Do you have a link that describes what happens in some detail. The best I have been able to come up with was anecdotal data let to from the WLW web site. There must be some article that was published in some trade magazine. My questions are:

The 50 KW transmitter supposedly has 60 some modules of about 1KW each. How does this jive with being able to get the 200KW PEP that is required for 100% upward modulation? Does the combiner add voltage or power? Seems like it would be voltage, but then the impedance a module sees would depend on how many are active at a given time.

What is the digital sampling rate? Seems to me they need a high power bandpass filter to get rid of the sampling frequency after the combiner.

BTW, I think a lot of people are going to confuse this with Digital AM.

Hi Roy,

Going back to the Slick discussions of last winter, Was that you who made the statement that you can have 100% re reflection from a transmitter, even if it has a 50 Ohm output impedance? At first I thought this was all wet, but after making some low power experiments, I am convinced it is true.

As for the ground wave- perhaps I am using the wrong term in describing the
regular (non enhanced) communications that takes place on 6M and up.
On 6M I can regularly work out to 300 miles or so w/o the aid of sporadic E,
aurora or other ionospherically propogated signals.
The ARRL Antenna Handbook describes ground wave as:
"...any wave that stays close to the earth, reaching the receiving point
without leaving the earth's lower atmosphere."

Kraus doesn't address VHF ground wave that I can see.

Perhaps scatter mode might be a better description- in this case tropo
scatter.

To obtain a conjugate match it is first necessary to know what the source impedamce is. How or from where is that elusive figure obtained?

It is not given in a transmitting tube manufacturer's data sheets. Perhaps it doesn't matter what it is - not needed?

Two points of clarification. The PAR design is not a half wave antenna. It is longer than a half wave- that length combined with the isosceles triangle shape yields an excellent omni pattern and a bit more BW

The 3 loop haloes were not 3 turns. The loops were configured as a folded dipole in order to increase the inherently low feedpoint R (10-15 Ohms) of a single loop. There is no increase in gain from doing this.

That definition is very misleading at VHF, since normal tropospheric refraction takes place entirely in "the earth's lower atmosphere" but generally doesn't involve ground at all. It's a gradual bending of the space wave.

>Kraus doesn't address VHF ground wave that I can see.
>
>Perhaps scatter mode might be a better description- in this case tropo
>scatter.

That isn't quite it, either, because "scatter" has a specific meaning which doesn't fully apply to this complex (and varying) mixture of propagation modes. In fact, no attempt to label VHF/UHF propagation as one single mode can ever be correct.

Thanks Charles, I got the package Saturday. I did a reset on the microphone per the instuctions and it works fine now. There is one catch though. I went to the Shelby NC hamfest this weekend before I got your post and was able to purchase an entire IC-229 radio cheaper than I could get a replacement microphone. Now I have two and they are both fully functional.

From the IEEE Dictionary:

"The ground wave can be decomposed into the Norton surface
wave and a space wave consisting of the vector sum of a
direct wave and a ground-reflected wave."

Looks like you are using the correct term and others may
not be.

Yep, the IEEE Dictionary says the "ground wave" possesses a
space wave component. "From a source in the vicinity of the
surface of the Earth, a wave that would exist in the vicinity
of the surface in the absence of an ionosphere. The ground wave
can be decomposed into the Norton surface wave and a space wave
consisting of the vector sum of a direct wave and a ground-
reflected wave."

Maybe you could revise your definition of "ground wave" to
agree with the IEEE? The IEEE dictionary says the "ground wave"
is defined to be what would be left if we took away the ionosphere.
It says the ground wave *includes* a component of the space wave.

It is true by definition. All reflected power incident upon a
transmitter is re-reflected, by definition. Never mind that
reflected voltage can cause an over-voltage condition and/or
reflected current can cause an over-current condition *inside*
the transmitter. By definition, any reflected power dissipated
in the source after making a round trip to the load was never
generated to begin with.

If no reflections are allowed to reach the source, the source
impedance doesn't matter (except maybe for efficiency).

> It is not given in a transmitting tube manufacturer's data sheets. Perhaps
> it doesn't matter what it is - not needed?

Install a matching network that achieves a quasi-conjugate
match between the network and the load. That's what I do. :-)

Hi OM,

I kin take it ;-)

: your conclusion above doesn't just _appear_ to
>be wrong, it IS wrong. 100% wrong.

Hmmm, in light of what is about to be said by you this continues to be
amusing.

>How do I know? I was the author of all of the brochures and technical data
>sheets for Harris' entire FM product line for the ten years before I
>retired.

Yes, your patter sounds like a publicist rather than a design engineer
- I've snipped your commercial fluff as it is pretty soft still.

> It
>is designed for a 50 ohm load.

Imagine THAT! Of course I won't hold my breath for your explanations
WHY (or -gasp- how) it is designed for 50/75/100/300 Ohms and not just
slap the output into any load - that would be an engineering issue of
matching which seems to be foreign to your discussion. Glad to see my
inclusions of so much of your copy brought back you memory that
rejected this:
On Sun, 5 Sep 2004 11:25:02 -0500, "Richard Fry" <rfry@adams.net>
wrote:
>The source impedance of most transmitters is not published even today.
I can accept that perhaps under your hand it was not, but Harris has
returned to the fold of conventional design specifications:
MW-10B SPECIFICATIONS
RF OUTPUT IMPEDANCE: 50 ohms, unbalanced.
Other output impedances available on special order.

Harris Platinum Z FM transmitter
100 ohm output impedance (unbalanced)

HARRIS SW-50 A
RF Output Impedance 300 ohms balanced, 2.0 to 1 maximum VSWR
Don't bother rummaging up you own drafts lingering in the musty
corners of the web, there are newer spec sheets available that easily
eclipse you in numbers to the contrary, but typical engineering

regards for specifying the output impedance.

I would suggest you review the works of a real engineer, Geoff Mendenhall (you know, the guy you dissed) who explicitly offers formula and specifications that correlate to current Harris equipment design considerations for matching source Z to load Z. This has been fairly common material available from Terman (One of Geoff's references) for 70 years now and even the digital age has not changed this:

It sounds pretty simple, in fact,
each module has a torroid (coil) which is the load for that module; all those torroids are lined up and an iron pipe is run through these torroids so that the combined output of all the modules is coupled into this pipe. One end of the pipe is at ground, the other end is the RF output of the transmitter. There is an output network to match impedance of the pipe, which is probably only a few Ohms, to the required output impedance which is usually 50 Ohms, although sometimes high power transmitters are set up to provide 75 Ohms, once in a while even 300 Ohms, to drive an open wire type transmission line system.

From the Goatman:
"It was necessary to determine the plate
load impedance (formula) = 1000 Ohms
where Emin min drop across the tube in saturation
I1 ac plate current.

"Since this Zp was to be coupled into a
Z output of 50 Ohm, a impedance transformation
of 20:1 was needed."

Perhaps this is too many words for the publicity department style sheet, but to engineers there isn't an iota of difference in the design considerations of the final over the course of 1968-2004. It goes much further back than this - we will skip that so as to not appear to be roughing the receiver.

However, to this subject I am quite used to the rebuttal "You are not going to change my mind." Impeccable logic such as this and variations offered by you have scant foothold in the sweep of time. I especially enjoy the sharp swerves to avoid the Goatman's simple expression above. Reminds me of the Chinese contortionist acts that used to be the staple of the Ed Sullivan show.

Thank you - that's a new one to me.

So what does the IEEE define a "Norton surface wave" to be?

Ground wave is a broad term, but it is how VHF and UHF usually propagate.
Ground wave is a general term for several means of propagation. Surface
wave is what you are really talking about when you mention Ground wave.
Space wave, atmosphere ducts and other means near the earth are all part of
the Ground wave term. The Sky wave is usually the broad term for
reflections off the ionosphere and other reflected modes from high above the
surface.

For vertical or horizontal there is very little differance in which is used
at VHF and above. Noise is usually vertical polorised so horizontal for the
RF is usually used . Vertical is used so the simple vertical moble whips
could be used for all around coverage.

Ian White, G3SEK wrote:
> So what does the IEEE define a "Norton surface wave" to be?

"Norton surface wave - a guided EM wave produced by a source over or on the ground. It is the non-geometrical optics component of the ground wave."

"geometric optics - the treatment of propagation of light as rays. Note: Rays are bent at the interface between two dissimilar media or may be curved in a medium in which refractive index is a function of position."

Presumably, there are no geometric optics involved in RF emissions from an antenna. Therefore, for an RF antenna, the Norton wave equals the surface wave. The surface wave and ground wave are NOT the same thing. Besides the surface wave, the ground wave contains part of the space wave which itself consists of two parts, direct and ground-reflected.

So according to the IEEE, it is not ground wave Vs sky wave. It is surface wave Vs sky wave. Ground wave = part surface wave and part sky wave.

I picked up a vertical antenna today from a fellow ham who had it stored outside !! not in use.
I have the 3 part numbers of the coils - 10M (870138). 15M (870135) and 20M coil (870369). There is also a 40M coil on top of the flat washer with no part number on it. The flat washer has holes which appear to have been a groundplane or a cap. hat.

any idea what I may have?? I have tried the net with these numbers to no avail.

Thanks for the compliment, Reg, that you prefer to take my word for it. However, the reason we include the manufacturer is not as a gratuitutous advert, but to distinguish between the Cadillacs (Hewlett-Packard and General Radio, among a few others) and the non-descripts. The Cadillacs are professional, precision instruments, which, when used by knowledgeable people, provide data that can be relied upon.

Without knowledge of the quality of the measuring device the reader is justifiably suspicious of the data.

I guess I'll have to repeat it for emphasis, Reg, but if the drive level is set
so that when the tuning and loading of the pi-network is adjusted to deliver the
maximum available power is within the normal operating range, there is a
conjugate match. In this condition the source and load impedances are equal.
This condition is by definition and proved by measurements.

If you like I'll send you a copy of the test procedure and the data.

At the RCA Labs antenna lab Dr. Siulola's name was held in reverence, but I never had the opportunity to meet him. After initially being at the RCA Labs antenna lab I originated the antenna lab at the new RCA Labs spinoff division, the Astro-Electronics Div, which produced the world's first weather satellite, TIROS 1, of which I developed the entire antenna system. However, I began that development at the RCA Labs antenna lab prior to the AED spinoff. I was working there along with Jess Epstein, of the Brown, Lewis, and Epstein group who performed the ground radial experiment that set the FCC standards for radials that still exist today.

I also spent time at the Moorestown antenna lab, working on the development of the Lunar Rover dish antennas. On its finish I performed all the final pattern, gain, and ellipticity measurements prior to shipping them to NASA.

Yep , Tam, it's correct. The internal resistance in Class B and C amps has two parts, 1) the cathode-to-plate resistance, which is dissipative, and 2) the non-dissipative resistance established by the V/I ratio within the pi-network tank circuit--a high resistance at the input and a low resistance at the output. The V/I ratio also establishes the slope of the load line. Consequently, the reflected power reaching the network output is not absorbed, but instead adds to the power delivered by the generator. Although powers are not generally considered to add, they do in this case, because their respective voltage and current phasors add. If the reflected voltage and current phasors are not in phase with those from he source, the only result is that the source is mismatched to the load and reduces its delivery of power. Readjusting the tuning and loading controls brings the out-of-phase phasors in phase, establishes a conjugate match and the source again delivers the maximum available power.

Hi OM,

If you simply follow the reference trail of those trade publications
(the design guides used by the engineers who did the actual work) you
would find PLENTY of source Z discussion:

from Harris White Paper:
"High Linearity RF Amplifier Design"
referencing
"Advances in AM Modulation Techniques to Improve Digital
Transmission of HD Radio and DRM"

"The poor antenna match will create a significant ripple in the
transfer characteristic of the main power amplifier. If that
amplifier itself has a poor output match to 50 Ohms
[the succeeding discussion gets into the inability of feed
forward correction to accommodate to this condition and the
introduction of an expensive isolator and lowered efficiency]
.... Alternatively, the amplifier itself could be modified to
improve its output match."

From Harris White Paper:
"Improving Efficiency With Split-Level Combining"
referencing
"High-Linearity RF Amplifier Design" (op. cit.)
and
"RF Power Amplifiers for Wireless Communications"
ppg. 31-32, 110
Discussion of load pulling to determine the "source impedance."
pg. 99-103 , Figures 4.21 & 4.23
Discussion of the source transformation from source Z 4 Ohms to
load Z 50 Ohms. Amplifier exhibits an 78% efficiency.
and
"Feed Forward Linear Amplifiers"
"Frequency ripple is one of the principle factors that limit broad
band signal cancellation and hence feed forward performance."
....
"As previously discussed, to prevent loss of power due to

impedance mismatches the input and output impedance of a device
should be equal to the characteristic impedance (e.g. 50 Ohms)
of the source and load to which it is connected."

From Harris White Paper:
"REDUCING FM IBOC TRANSMISSION COSTS WITH THE PROPER
CONFIGURATION AND LINEARIZATION TECHNIQUES"
referencing
"Feed Forward Linear Amplifiers" (op. cit.)
and
"RF Power Amplifiers for Wireless Communications" (op. cit.)
and
So on and so on and so on (no deviance from commonplace
design considerations that have been described for generations).

======================

My dear Cecil,

99% of the contributors to this newsgroup, particularly the professionals, should make appointments to see a shrink. Problem? - the inabilty to grasp what is staring them in the face.

It's a sad reflection on the present state of electrical engineering educational facilities in the Western world. Never mind, there's still hope, the Chinese, Vietamese, Hindu's, Indianesians, etc., will help us to sort out such trivial matters as vswr. The problem of sharing energy resources will take a little longer.

I have just opened a bottle of Chilean, Isla Negra, Cabernet Sauvignon. I can't read what else it says on the label. But we musn't neglect our good (South) American near-neighbours and friends.

I am listening to the BBC. The World's finest educational facility although it sounds more like the VOA than the VOA.

It seems that a very large proportion of the Virginian forefathers were of the criminal classes, convicts, conveyed in chains, who shared there lives on arrival with negro slaves. Life expectancy in Baltimore and Maryland was about 7 years. Between 50,000 and 100,000 convicts were exported to the Land of the Free. They were present at the Alamo and assisted at many other places to rid the land of the original inhabitants. Is this proudly recorded in your children's history books?

Shot any rattlers lately?

From a sincere European friend of all USA citizens, descendents of convicts, SWR worshippers, conjugal-match adherents, voters even for Bush, or otherwise.

Reply not needed.

Hi...first post...I was taking a first run at 4nec2 last nite, and since I am interested in modeling a short vert for the 5th wheel (I just retired), I tried the "vehicle.nec" and the "grdplane?.nec". According to the notes, these models were converted to nec2 by K6STI. But, at least right out of the box, they both produced errors. By looking at the Validation log, these errors were associated with adjacent segment lengths, or length to radius in segments. My question...since I am new to Nec2 (but not to Elnec or Mininec), did I miss something in the Nec2 program setup, or do these (2) models not normally run without tweaking them? Thanks
Bob, VE5AG

Hello All,

Reg's post above just gave away his cover as an undersea transmission-line engineer that renders his failure to comprehend SWR, conjugate match, oops, I mean conjugal match, completely comprehensible.

I know his relevation was totally inadvertant, but it's evident to this SWR worshipper that he's really a situp comedian empowered with an overdose of, what did he call it, Kavurnay Sawvignun? He admitted he couldn't read what was printed on the bottle.

So let's all take pity on this sensitive guy who's beyond his depth in trying to fathom our attempts to bring him up to speed on the vocabulary required for speaking intelligently on the vital engineering issues we discuss on this important media of understanding.

God bless the Cween.

Walt

Man, Wes, I sure ran of the road and totalled the Caddie on this one, didn't I?

However, what happened to the Rolls-Royce? Did the Queen boot it out? As I recall it from my pre-teen days, it was definitely a Brit. And how did it manage to land in Deutchland? Or did Neville Chamberlin manipulate this one too?

Walter, W2DU wrote:
"The internal resistance in Class B and C amps has two parts, 1) the cathode-to-plate resistance, which is dissipative, and 2) the non-dissipative resistance established by the V/I ratio within the pi-network tank circuit -- a high resistance at the input and a low resistance at the output."

It`s true that a parallel resonant circuit constructed of ideal inductance and capacitance has high (infinite) impedance and no loss. The configuration of the high impedance in series with the load limits output. But, we use imperfect components and we seek a limiting impedance equat to the 50-ohm load, not an infinite impedance.

My take on the non-dissipative impedance is that it comes from the switched-off time of the Class B and C amps. During this time in each cycle, no current flows through the amp to cause loss. Likewise, there is no current from the amp (actually it is a switch operating on and off at a radio frequency) to the load or tank circuit. The tank circuit cleans up the pulse mess, filling gaps in the RF cycle.

Thanks Stew for your valient attempt to clarify the meaning of Quality in the electrical measuring instrument field in terms of the motor industry. Unfortunately the motor industry, as is everything else, is now in the hands of the International Corporations and is all mixed up.

We are left only with the remains of the confusion with the quality description "Rolls Royce" which all nationalities understand. It remains for the same reason that the English language remains. Rolls Royce appeared at the end of the British era of engineering supremacy which began with the Bimingham Wire Gauge around the time of the French revolution and continued through the beautiful Boulton and Watt reciprocating, condensing steam engines which ruled the Earth for 80 years, as did Britannia's well-engineered battleships and 16-inch, 18-inch guns.

Our German friends took over at the battle of Jutland and the Bismark incident. But the optical qualities of Zeiss rangefinders probably had something to do with it.

But to avoid an international incident, it should be stated the ordinary engineering educated Englishman quite understands the meaning of "Cadillac" although he may not have the foggiest idea of where the name came from. Was it named after a red-indian tribe such as Cincinatti or Detroit?

By the way, I sometimes think that mention or reference to a particular measuring instrument or the name of a prominent author implies a lack of self-confidence and conviction in what one is stating.

As for me, I rarely make such mentions if only to avoid the danger of mis-quoting. The responsibity is then entirely mine.

Although I may jokingly profess ignorance of American electrical measuring instruments, for several years I was the Government-approved Head of Laboratory of a measurement standards laboratory of second echelon to the British National Physical Laboratory. I was familiar with the excellent qualities of HP, GR, Fluke and similar instruments. I played an original part in the conversion of the assessment of National worst-case measurement uncertainties to statistical uncertainty asssment. But I don't brag about it.

Actually, if it were isolated in museum glass case perhaps, but the loaded Q, by design, is less than 20, often less than 10, and in the case illustrated by Mendenhall's FM transmitter = 2. Loss comes to it by nature as a practical necessity of moving power (transmitting) to the ï¿½ther.

>The configuration of the high impedance in series with the load limits

The impedance transform of coupling that changed from plate resistance to load resistance is quite capable of reciprocal transformation (at least in the rigs of transistor persuasion) to allow return power from load Z to match towards the source Z. This is the natural progression of linear design.

>My take on the non-dissipative impedance is that it comes from the

By the nature of reciprocity, loss must follow from reflected power returning through it to a known dissipater, the cathode-plate. If that cathode-plate is available only intermittently during cycles, reciprocity is fully functioning through the same available flywheel of this loaded Tank.

All should notice that if this scenario is NOT working as described, the caloric demands of reflected power would resolve in a high energy arc along the way (no one has ever experienced this?). This may displace WHERE the dissipation occurs, but it does not render reflected power an inert concept.

All such descriptions can be described in a bulk component model, it is still the same heat (only the remote arcing becomes an enigma some would sweep under the rug).

Denis -

You may be describing the HyGain "AVQ" series of HF vertical antennas. You can check the HyGain web site (now owned by MFJ):
http://www.hy-gain.com/products.php?prodid=AV-14AVQ

Part numbers for the Hy-Gain AV-14AVQ antenna (these numbers are VERY close to your part numbers)
http://www.hy-gain.com/parts.php?prodid=AV-14AVQ

HyGain did make (at one time) a 18AVQ, which was a 14AVQ with the 40 meter trap -- so it would work on 75/80 meters.

Technical Support: hygain@hy-gain.com

Unfortunately, MFJ is NOT known for quick technical support (as stated on their web site!)

"NOTE: There is a two to four week response time for all technical support emails. If this is not fast enough for you, please call us on our technical support lines listed below."

Who makes the Rolls-Royce jet engines now?

Our company`s first jet airtcraft was a Vickers Viscount prop-jet. We were in a long cue waiting for one when a wire from Vickers came saying Cubana Airlines had defaulted on an executive outfitted Viscount for Fidel Castro. Did anyone in the cue want the aircraft? Our chief pilot asked the dhairman if he could buy it? The answer was yes. It was already outfitted almost as we would have done anyway except our labeling would have been in English instead of Spanish.

I remember landing in Antafagasto Chile right after we got the Viscount. The Shell Oil tank truck charged out and the operator asked our pilot, Charlie Walling, which grade of kerosene he wanted, JP-1,2,3,or 4, etc. Charlie replied he would have to consult the owners manual, a really big tome. The book said any grade is fine for the Rolls-Royce turbines. Charlie told the Shell guy to fill it with whatever grade he was long on. Sure enough, the engines lit right off and ran fine. Most remarkable was after a flight from Houston, all the engines only required about a teacup of oil. Our piston engined aircraft would have consumed gallons of oil on the same flight.

Germans respect British motors. The Messerschmitt Bf 109 resulted from a competition spurred by a request for proposal to build a new German fighter aircraft. The Messerschmitt was one of 3 designs from competing manufacturers who built prototypes for the competition. All 3 featured British Merlin engines! The production Bf 109 had a 1475 hp Daimler-Benz engine, but a Merlin powered it to victory in competition.

Hermann Goering declared in Berlin, "If the enemy bombs this place my name is Mud." Later, as he arrived in a bomb shelter, he said,"Let me introduce myself. My name is Mud."

A famous German fighter leaded once asked his commander for a squadron of Spitfires!

Debunking mode ON

Cincinnati, Ohio (not Cincinatti) was named not after what we in Canada call a First Nation but instead after the Society of the Cincinnati, an organization formed after the American War of Revolution (1776 and all that). The organization was composed of former American Army officers. The Society of Cincinnati, in turn, took its name from Lucius (Titus) Quinctius Cincinnatus, a farmer and former consul who was asked to leave his fields to become dictator to defend Rome against outsiders, in 458 BC. Under his command Rome's enemies were defeated, and 16 days later he returned to his farm.

Cadillac, Michigan was named after Antoine Laumet de La Mothe Cadillac, a Frenchman established a settlement near what is now Detroit, Michigan, in 1701, and the automobile was named after either the city or the French settler.

Debunking mode OFF

David
(1) born in Cincinnati, Ohio in 1935
(2) licenced as W8EZE in that city in 1949
(3) learned about Cincinnatus in grade school
(4) wishes that certain US politicians would just return to their ranches where they could only harm rattlesnakes and cactus plants

No it doesn`t, but it doesn`t require its acceptance back in the transmitter either.

I`ll repost my earlier posting as near as I can reconstruct it. It seems to be lost in cyberspace.

Walter Maxwell, W2DU wrote:
"Consequently, the reflected power reaching the network output is not absorbed, but instead adds to the power delivered by the generator."

My explanation for the above, which is my observation too, is that an energy wave experiences a phase reversal between the volts and amps which it will generate after reflection. That fact makes Bird`s directional coupler in its wattmeter work.

The transmitter`s output isn`t receptive and won`t absorb a wave that produces out-of-phase volts and amps, so the reflected wave is re-reflected from the transmitter, placing its amps and volts back in-phase.

The newly minted RF and the twice reflected RF are similar, both having their volts and amps in-phase. So, the similar RF constituents merge to have a go at the reflection point.

The original MGs were built right here in Abingdon-on-Thames, and the big factory where the Minis are made is just up the road in Oxford. Lots of local people either are or have worked in the car industry... and some of them are also hams.

Even when R-R Motors was an independent company, it used part of the big Oxford factory. That much larger company eventually bought R-R, but in turn has done deals in which first Honda and then BMW provided transfusions of new technology in return for a large share of the company itself. However, the company still makes its own cars under the name Austin Rover.

R-R Motors has always been a separate operation, with very different ways of doing things. For example, all the stories you've heard about countless coats of paint, each one hand-applied and hand-rubbed, are true. The comforting thing is that down at the other end of the factory, cars for the rest of us are being stamped out with modern high-tech, high-bake paint jobs that will wear far better.

No, that's not quite true. The original models were created by K6STI.
These models then were converted by myself to (4)nec2 models already
some years ago, using the 4nec2 program.

> least right out of the box, they both produced errors. By looking at

> them?

No, you did not miss something. When converting Antenna-Optimizer
files to (4)nec2 input files, 4nec2 used a maximum of 10 segments per
half-wave. For the vehicle file, this produced big changes in segment
lengths for the elements at the backside of the car, which in turn
could produce Nec-2 inaccuracies. To avoid this problem, you could
manually tweak the segment count(s) or length(s).

I made a slight change in the new 3.4 version, so in the near future
one is also able to specify the nr of segments per haf wave when
converting AO files.

Another workaround for this drawback is to convert the *.ant file,
then open the corresponding *.nec file using the geometry editor,
select the whole structure and move it a short distance to the left or
right. This way the segment counts for all elements will be
recalculated according the segment density as specified in the
'segmentation' option.

Concerning the GndPlane file the vertical element was originally
specified as 1 inch in diameter, the sloping elements are specified as
#12. The change in radius for these connected elements can produce
error's when used with Nec2.

**

Furthermore, thanks for the message, because this also anbled me to
detect and solve a bug, related to the use of temporary files on
windows-XP.

Greetings from the Netherlands,
Arie.

Wonder why we have protection circuitry in transmitters?
The superposed forward voltage and reflected voltage can damage an unprotected transmitter. The superposed forward current and reflected current can cause over heating in an unprotected transmitter.

The transmitter sees whatever impedance it sees and that impedance can be highly reactive. The superposed voltage can be high or low. The superposed current can be high or low. The phase between the superposed voltage and superposed current can have lots of values.

Just a for instance - assume the transmitter is putting out 70.7v in phase with 1.4a at zero deg. The arriving reflected wave is 50v at 90 deg and 1.0a at -90 deg. The load seen by the transmitter is 86.6v at 35 deg and 1.72a at -35 deg. Over voltage and over current exist at the transmitter output. The forward power is 100w and the reflected power is 50w. The net power being delivered to the reactive "load" seen by the transmitter is 86.6*1.72*cos(70.4) = 50w.

The math model is trying to dictate reality. It is supposed to be exactly the opposite. There is no magic barrier that automatically rejects reflected energy from a transmitter. Reflected energy arriving at the transmitter can drastically alter the impedance away from the designed-for load impedance. The transmitter sees one of the transformed impedances that exists on the SWR circle.

Note that the problem disappears in a matched system where reflected energy is not allowed to reach the transmitter.

Richard Clark wrote:
"In a reality of 359 other possible phase angles, how does a transmitter happen to always be in-phase to any reflection?"

Connect any generator to any resistor, and current in the resistor is in-phase with the applied voltage. The Zo of the common transmission line is a reasonably good resistance. At radio frequencies, Zo is independent of frequency.

The current in the incident wave is always in-phase with the voltage applied to a transmission line. The current in the reflected wave is always 180-degrees out-of-phase with the reflected voltage. It makes no difference which was inverted by reflection, the volts or tha amps, one, and only one, of them was flipped upside down. The transmission line can and does handle the reflected wave.

Standing waves display interference between incident and reflected waves whiich ideally have in-phase and out-of-phase constituents.

The fact that the Bird wattmeter works is evidence that the theory is correct at least until a better theory replaces existing theory.

Best regards, Richard Harrison, KB5WZI

Hi Richard,

In a world of mismatches, how does it happen that the transmitter always sees an in-phase, resistive load? If this were the best of all worlds, tuner manufacturers would be out of business, salesmen would starve and Reggie would have nothing to write about.

To do so, they would be in-phase and not out-of-phase. Entirely possible if the transmission line is the right length.

If the reflected volts are in the same phase as the newly munted volts, which are larger? With a reflection coefficient of 1, and a lossless line, the open-circuit value of transmitter volts would face some lower value of line volts on opposite ends of the internal impedance of the transmitter. Which way does the current flow?

Theory is that it flows from the higher to the lower. That is, from the transmitter to the line.

It doesn`t. You can put a capacitor directly across its output terminals, and the transmitter will energize the capacitor. But, a transmission line is not a capacitor unless it is a short open circuit, or the equivalent. A transmission line is a distributed network of inductance and capacitance. This network transfers emergy in bucket brigade fashion. The "brigade" presents a resistive impedance to both the incident wave and to the reflected wave. Zo is an enforcer.

Hi Richard,

And so it would seem that a too-short antenna would act likewise.
This, then, returns us to my original question for this, a very simple example that has a currency that is frequent enough in our experience:
how does a transmitter happen to always be "in-phase" to any reflection?

Nope, they don't have to be in-phase. The reflected voltage can arrive with any phase with respect to the forward voltage. You trimmed out the example I gave. I will repeat it so you can study it closer.

Just a for instance - assume the transmitter is putting out 70.7v in phase with 1.4a at zero deg. The arriving reflected wave is 50v at 90 deg and 1.0a at -90 deg. The load seen by the transmitter is 86.6v at 35 deg and 1.72a at -35 deg. Over voltage and over current exist at the transmitter output. The forward power is 100w and the reflected power is 50w. The net power being delivered to the reactive "load" seen by the transmitter is 86.6*1.72*cos(70.4) = 50w.

In the above example, the designed for output voltage is 70.7v and the designed-for output current is 1.4a. The superposed voltage is 86.6v, higher than the designed-for voltage. The superposed current is 1.72a, higher than the designed-for current. In this example, we have both over-voltage and over-current occurring *at the same time* even when the forward voltage and reflected voltage are 90 degrees out of phase. The superposed voltage is not smaller than the forward voltage until the phase angle between them is in the neighborhood of 120 degrees. Two superposed voltages with a 90 degree phase angle are *always* larger than either voltage component, i.e. SQRT(V1^2+V2^2) is always larger than either V1 or V2.

The superposed voltage will be higher than the forward voltage for any phase angle from zero to 90 degrees. At some phase angle higher than 90 degrees, in the neighborhood of 120 degrees, the superposed voltage starts to decrease.

If you sit down and draw these phasors on a piece of paper, you will discover that you are mistaken. It appears that you are thinking one-dimensionally instead of two-dimensional phasors.

It doesn't. The reflected voltage can obviously be 90 degrees
out of phase with the forward voltage in which case, the
interference term equals zero, and the superposed voltage is
SQRT(Vf^2+Vr^2), i.e. greater than Vf. (The argument reminds
me of Gary Coffman's one-dimensional "spitting up the fire
hose" argument.)

> Standing waves display interference between incident and reflected waves
> whiich ideally have in-phase and out-of-phase constituents.

In the following, the interference term equals zero.

XMTR--------1/8WL 50 ohm lossless coax------291.5 ohm load

Forward power = 100w, reflected power = 50w.

Vf = 70.7v at zero degrees, If = 1.4a at zero degrees

Vr = 50v at 90 degrees, Ir = 1.0a at -90 degrees

Superposing:

Vtot = SQRT(Vf^2+Vr^2) = 86.6v over-voltage condition

Itot = SQRT(If^2+Ir^2) = 1.72a over-current condition

The phase angle between Vtot and Itot is about 70.4 degrees,
i.e. the source sees a highly reactive impedance.

Vtot is NOT in phase with Vf, Itot is NOT in phase with If,
Vtot is NOT in phase with Itot. Vf is NOT in phase with Vr.
No two voltages are in phase. No two currents are in phase.

Cecil is right. The third side of a triangle can be longer or shorter than one of the sides.

I should have said, it is entirely possible that the superposed forward and reflected voltages can damage an unprotected transmitter, The reflected voltage can add to the forward voltage applied to the transmitter.

The phase of the reflected voltage should be out of phase with the transmitter source voltage to maximize the volts across the internal impedance of the transmitter if we want to damage an unprotected transmitter.

Best regards, Richard Harrisin, KB5WZI

> transmitter.

Now assuming, as Richard H. logically did, that we don't want to damage an unprotected transmitter, let's introduce the concept of an active match Vs a passive match.

The match at the transmitter output is passive, not active. Consider the following system:

XMTR---1/4WL 300 ohm feedline---1800 ohm load

What does it really mean when we say that the XMTR "sees" 50 ohms?

It means that an interference pattern is established at the XMTR that re-reflects (re-directs) the reflected energy back toward the load. The transmitter has absolutely nothing to do with that reflection.

We can reconfigure the system as follows:

XMTR---1WL 50 ohm feedline--+--1/4WL 300 ohm feedline---1800 ohm load

Now we can see that the match is passive and the XMTR has nothing to do with the match.

Destructive interference on the XMTR side of '+' eliminates the reflections. The resulting equal magnitude of constructive interference on the load side of '+' re-reflects (re-directs) the reflected energy back toward the load.

Optics engineers understand interference. Seems RF engineers might not fully understand interference. Interference is the cause of the elimination of reflections in optic systems. Interference is the cause of elimination of reflections in RF systems, including at antenna tuners.

Hi Fellas,

Your old buddy Dr. Slick is back again, pleading on his
hands and knees for more sage advice from the masters of
antenna design, YOU GUYS. (well, at least a few of you...
hehe! The rest you have to ignore...)

Ok, so my wireless D-link modem computer is downstairs from
the wireless router, and so the signal is very low using just the
antenna stub that it comes with.

So i found this:

http://turnpoint.net/wireless/has.html

And this Yagi-Uda scaled for 2.4 GHz:

http://seattlewireless.net/index.cgi/MicroTVAerial

Someone told me that the Yagi-uda wouldn't be as good
as the cantennas, as the later gathers more RF power, being
a type of reflector and such.

Since the Nalley's Big Chunk "Beef Stew" design won,
i think i will try that, with a funnel attached as on this
page:

http://www.saunalahti.fi/~elepal/antenna2.html

Any knowledgable advice greatly appreciated.

Slick

Corner reflector. Cardboard and tin foil. 15 minutes (if that).

About +15dB gain.

www.google.com/search?q=corner+reflector

If it works, then you can investigate other (more permanent) solutions if
you like.

Cecil, W5DXP posed a problem in which a transmitter seeking a 50-ohm load (I suppose) is attached to 1 WL of 50-ohm cable which is attached to 1/4-wave of 300-ohm feedline which is attached to an 1800-ohm load.

Cecil wrote:
"Destructive interference on the XMTR side of "+" (where 50-ohm cable meets the 300-ohm Q-matching section) eliminates the reflections."

It seems to me, the product of 50 (the cable Zo) and 1800 (the load Z) is 90,000. The sq.rt. of 90,000 is 300 (the Q-section impedance). The numbers are right, so in my opinion, the Q-section converts the 1800-ohms to 50-ohms. This is the 50-ohms likely prescribed for the transmitter`s load. The 50-ohms presented by the Q-section to the cable should result in a match and thus there should be no reflected energy in the 50-ohm cable to cause interference. The reflections should all be in the 300-ohm Q-section.

Best regards, Richard Harrison, KB5WZI

|
|Hi Richard,
|
|Even here, the Goatman offered in his notes that his finals tank
|(actually a series resonant Z match) offered a loaded Q of 2! (If I
|read his scribblings correctly.)

Yeah and he also calculates

(http://www.techatl.com/wrek/docs/gnm69_25.htm)

the required plate load resistance as:

Eb
Rl ~ -------
Idc

Which for class C is off by about a factor of 2, but with Eb = 2500
and Idc = .25, he does the division and comes up with Rl = 1000. Hey
what the heck, what's a factor of 10 among friends.

If the calculation is done more accurately:

Eb - Eg2
Rl = ---------
K * Idc

Where K = 2 for Class C and
Eg2 = 300 (screen voltage)

Then Rl ~> 4 Kohm

Since the minimum output capacitance (Cp) of a 4CX300 is 4.5 pF, the
parallel equivalent of Rl and Cp is Rp ~ 3920, Xp ~ -388.

Thus the minimum possible Q ~ 10, which to someone who has built a few
VHF amplifiers, sounds much more plausible.

For example here's one I designed and built not much later that the
WREK(ed) transmitter.

http://www.qsl.net/n7ws/K7CVT_Amp.html

But it gets worse. Try as I might with the component values he specifies, I cannot develop a plate load Z anywhere close to what is necessary. He has a lot more inductance that he thinks, so maybe that helps and I suspect his output lowpass filter (seen in the photos but not on the schematic) is part of the matching network.

I'm really surprised that with the construction and documentation presented he could get FCC type acceptance.

Exactly, thanks to destructive interference. In S-parameter terms:

b1 = a1*s11 + a2*s12

where b1 is the normalized reflected voltage back toward the source
and is equal to zero because complete destructive interference between
a1*s11 and a2*s12 causes their phasor sum to equal zero.

Those two voltage components cancel to zero toward the source. That
destructive interference is necessary and sufficient for a matched
system. The result is constructive interference toward the load.

Hi Wes,

Still and all, a good story of the exploit.

Well given the measurements, it seemed some filtering was necessarily
unmentioned. And given the FCC type acceptance (obviously allowed),
the measurements (or rather the quality of the gear) were sufficient.
I especially find the scrawled notes submitted with the acceptance
application a time capsule back to the days before computers (or
seemingly the IBM selectric).

Still and all, he described where he was going, and offered how he
thought he got there. To translate that to today's specifications
"missing" the output Z of transmitters (obviously part and parcel to
the canon of the design engineer who built them) because of their
irrelevance - that is a stretch of imagination right off the showroom
floor. And then to notice in the ad copy, they can build to other
output Z's...

I find the novel modulation techniques interesting though. Seems like
an alphabet soup of modes has sprung up over the years.

2991. What ground arrangements should I make for my 20 metre long marconi antenna.

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-08 13:28:00 UTC
From: Richard <nearlynews_email@ntlworld.com>
Message-ID: <2q8fkvFste59U1@uni-berlin.de>
Source record: 89812

Hi. I want to work 160, 80 and 40 with a 20 metre length of wire (fed into an atu) that is to be supported between a mast and a pole on the house chimney stack.

Here is a plan of my garden:

8.6 metres

```
_________________________________
\ x A |
\ |
\ | 5.8 metres
\ |
\ |
\_C_____________________B_|
```

6.4 metres

x is where the antenna will connect to the atu.

distance from x to A is 7.8m
distance from x to B is 9.4m
distance from x to C is 5.4m

the angle at x, from points A and C is 73 degrees, so any ground wires centered on point x would fan out 73 degrees..

Okay, what ground arrangements should I make? Do I drive in 2 or 3 2 metre ground rods at point x and as many ground wires 6 inches below the surface fanning out from point x, or what? Would I also connect a conterpoise wire or wires to point x running a foot or so above ground?

Thanks for any advice.

Rich.

2992. free standing pole for antenna to receive broadband access

Thats what I thought the first time I saw it done but this is the way the
power company checks grounds. It can be done in a safe manner. Also there is
equipment commercially made for doing this test. Ideally one should use this
approved equipment but there is no reason it cant be done with improvised
equipment with no more risk than taking a voltage measurement in a hot
chassis. Of course there are those who lack the ability to safely perform a
test like this and should not even be allowed in their service panel to
reset a breaker.

Hi Rich,

It might, but your atu might not. ATUs are not a one-size-fits-all
solution. In fact they fit very few problems that are not already
pretty close (and what you describe above and in other posts is
definitely not close). Maybe two bands will pull in, the others will
not (unless the loss of the ATU adds to the appearance of being
"tuned").

Using a cold water pipe is a bad idea and is not allowed by some local codes
even though it may be allowed by the national code. This is partly because
it should only be connected to the ground system at one point and it is too
easy to connect it at more than one. Also there is the possible interaction
with gas lines and plumbers and home owners sometimes modify plumbing in
ways that make them poor grounds..

Andrey wrote:
"I want to create horizontally polarized antenna, low profile, located above large ground plane. And I need it to be omnidirectional (sort of) and have sufficient gain in horizontal plane.

My frequency of interest is 900 MHz. The ground plane is a roof of a car."

A horizontal dipole above a metal car roof is a poor choice.

Polarization choice at 900 MHz does not affect signal range.

In the horizontal plane, the direct signal broadside to the dipole is cancelled by the reflected signal from the roof unless you elevate the dipole by 50 cm or so at 900 MHz. That`s almost 2 wavelengths. At that height, the omnidirectionality may not be even "sort of".

Better to use a vertical which has a signal null off its tip and maximum radiation in the horizontal plane. This can be a collinear made of 1/2-wave sections separated by 1/4-wave stub(s) for gain. As the wavelength is only 34 centimeters, this isn`t much of a problem. It could be made by bending a single length of stiff wire.

Best regards, Richard Harrison, KB5WZI

3000. Place the GPS antenna directly on the ground plane?

You won't harm the antenna by putting it directly on the ground plane.
So try it, and see if your signal improves.

I'm not familiar with the particular antennas you mention, but I'll bet
someone at sci.geo.satellite-nav would be.

Hi Larry- If what you really ment was a "Utility Pole" aka power pole, telephone pole, then once you have it planted, and you wish to mount a rotor on it, can be done quite easily, as long as you have the bottom pipe mount for your rotor. at the top of the pole, you will need to drill a couple of holes thru the pole , useing 5/8 bit. Next: you need a chisle - notch about 1 inch deep notch in the pole, perpendicular to the pole (horizontal) Now get couple of pieces of 5/8 inch all-thread- if you are good with a torch, bend a section of the all-thread into a circle, slightly bigger than the pipe to support your rotor (or find a metal smith to do it for you) and be sure to weld the end of this loop to the part where the circle started to be formed. On the notched end, insert your all-thread - DO NOT USE A WASHER! on the un-notched end, use a washer, and nut. Run your pipe thru the loops of the all-thread, then tighten the nut on the allthread. as the loops suck into the notchs of the pole, it will pinch your support pipe, and becomes quite tight! and will support at least couple hundred pounds! Another tactic used is get the mounting hardware from d.b. products for their db-222 antenna this will allow mounting a pipe to a pipe- now what you want is thrubolt to pipe. one of the looped pieces needs to be replaced, with a piece of channel iron, drilled to mate the rest of the mounting hardware parts, and then drilled thru the center for your thru bolt. Have seen these hold up with several hundred pounds of ice and not break! And, be sure to run a GOOD ground to this mount, for lightning protection! as info,
Jim NN7K

You don`t want to be electrocuted when holding an electric appliance and a cold water valve simultaneously.

My electric company, the former Houston Lighting and Power Company, writes:
"All services shall be properly grounded. Note - NEC requires grounding to a "metallic underground water piping system" if available. Acceptable alternatives include a driven ground rod which is preferred by HL&P Co. regardless of the type grounding electrode used. NEC requires that the "interior cold water pipimg system" be bonded to it."

That last point is the same in the UK. Gas and water supplies are never
relied on to provide an electrical ground, but they must be bonded to
the electrical supply ground.

Additional local bonding is also required for all metalwork in bathrooms
and shower rooms.

The wire to earth from your atu is a part of your antenna even if you don`t ground its far end. If you desire a strong vertical component to your radiation, put as many radials in your garden as possible to minimize the distance displacement current flows to reach a copper earth return wire.

No kidding. I added a laundry room and attached garage to my house. The former owner/builder had intentions to do something similar but had not for whatever reason. He had stubbed out hot water from the house (concrete slab on grade, pipes under slab) but not cold water.

I ran an exterior cold supply from the service entrance using PVC underground and copper inside. I added another ground rod and 100' of 4 AWG buried at the base of the new footing and grounded the new cold supply with it.

IMHO you can't have too many ground connections.

Hi.

I know the zeppalin antenna I described works when the top wire is a half wavelength or greater. I was just wondering if the set up (ie 10 metre length of top) might at least be a good as a 20 metre long inverted L (well, L on it's side) on 40, 80 & 160, using a not very good ground arrangement.

Thing with the zepp is that there is no ground losses. Thing is, ground losses with inverted L are probably replaced by greater atu losses? And of course the inverted L would radiate also from the vertical section which migh be useful. I do wonder of the two arrangements, which would be better. I wonder also whther I might not get a true balance on the open line when the top is less than half a wavelength.

Hi Rich,

You also need to consider the length of the transmission line (what
makes the Zeppelin work with your rig).

For 160 it is quite short, for 80 somewhat short; but being short is
not a sin in and of itself. What is a sin is what the tuner has to
put up with. Most ATU's only cope with up to 3:1 SWR. A short
antenna may well exceed that. Obtain a copy of EZNEC (using the free
version) and give yourself an education on what to expect.

You won't have a true balance unless you are feeding a true balanced
antenna (which a Zepp is not, nor an inverted L).

In what way better, They are not interested in a specific value in most
cases. Just a go -no go test. Plug the tester into an outlet, touch it to
the ground stake after isolating ground from neutral. Fuse pops or it
doesnt, Ground meets spec or it doesnt. Apparently there are lot of people
who think this idea is not so dumb since the tester they use is commercially
available, a fact that I mentioned in the previous post that you chose to
ignore.

Read up on the topic of linear loading. You can bend that wire back on itself and increase the total length of wire. There are discussions of this in ON4UNs Low Band Dxing book. One commercial example is the Cobra Ultralite at http://www.k1jek.com/.

I use a top center fed L. One side is horizontal and the other side is vertical. Fed at the top center with ladder line. Cebik has several articles on his site about center fed Ls. No ground plane, horizontal and vertical polarization, fewer nulls in the pattern. Very nice

I think the center feds make a lot more sense for multiband operation.

Hi Craig, is that fed with ladder line right out of the tuner? I'm hoping there is a best-fit arangement from my tuner to an inverted-L with either a top-fed through a 4:1 balun or end-fed without a balun. In either case the intention is to cover 2182khz with a 107' 1/4~ L. Any suggestions on the best arrangement for that work?

Thanks,

Jack

Thanks to all who responded. I see I've been misusing "ground wave" for a long time, in place of "surface wave". And my apology to those I've questioned about "ground wave" propagation at VHF/UHF. According to correct usage, it does indeed exist -- just not with a surface wave component.

Gosh, is my face pink.

You all were right when you wrote to use a balun and 75 ohm coax, not twinax line to run to the input of the radio. The ring connector on the OEM dipole is a copy-protection throwoff. The true connection is that one leg is _grounded_ to the sleeve/barrel/chassi, and the other is connected to the tip terminal. I determined this with a sewing pin to penetrate the dipole insulation and an ohmmeter.

But Don Foreman is instructing me in how to rewind my 300:75 ohm balun to 75:75 ohms for the open six element triple drive antenna so my face isn't red. That is, I am learning something.

Later, in my shop, I will install the balun core to the Wizard board and go back to the twinax, so that the Wizard can accept a the big antenna the way it is now, but with the plug in all the way instead of just part way, or a new flexible open dipole that is a true balanced dipole and doesn't have one leg grounded. It can be made from a bit of twinax, or the existing dipole can simply be soldered to a fresh TRS connector.

Do any of you know a software patch to get lower than 88 MHz on the Wizard? I'd like to listen to ATC.

Doug

You can go with ladder line right out of the tuner or to a short piece of coax to a balun, then to ladder line. I have about ten feet of coax to a 1:1 balun outside. The coax is easier to get out of the house and away from things that might unbalance the ladder line. Loss on such a short piece of coax is negligible even at high SWRs on HF.

Whether you use a 4:1 or 1:1 depends on the antenna and feedline. I use a 1:1. Your antenna will be the "right" length so the impedance at the transmitter end won't be too far off from 70 ohms. A 4:1 balun would be a mistake as it would lower the impedance making it harder to match the transmitter.

I have to ask, "Why are you using ladder line?" Usually it is only used when the antenna has a high SWR and we want to avoid losses in the coax. You won't have much of a mismatch, if any. I would think you would go with coax, you might not even need a tuner.

Thanks Craig - and if you could, please elaborate on these design considerations:

The antenna is not erected yet - still planning. I would choose a 1:1 balun if I used one at all with an end-fed inverted-L configuration. But if I configure the antenna as a sloper (same L-shape) and top-feed at the angle point, then I thought a 4:1 balun could help make 2182khz tunable on an antenna with dipole properties that is really too short (would have to be 107' each leg not 107' total, which is about all I can get at that location). Of those two choices, I had not intended to use ladderline for either, but would consider it if some benefit was possible. Ideally, the antenna would be desireable to cover 2-20mhz. No compromse on the 2182 end is worth the upper bandwidth though, with 5.7 & 8.9 mhz the other requirements that should not unduly strain a tuner under high tx power. The antenna would be primarily for 2182 - 4125 khz.. Thanks for any help.

3019. Available power from an RF field

What is the available power, Pa in picowatts, that can be extracted from a free space field of Ea microvolts per meter?

A reference I have says it is:

Pa = Ea squared multiplied by Ae (the antenna effective area) all divided by 2Zo, where Zo = 377 ohms, the impedance of free space.

My question is why 2Zo rather than just Zo. Is it because only half of the power in the field can be extracted and delivered to a load?

Hi Dale,

Are you saying that the old saturn halo was not 3 loops? It sure looks like it in the pictures that I have seen.

I know that your design (the Par Omniangle) is not the classic 1/2 wave halo, and does offer more advantages over a halo. I sure wish I had a 2m and 6m for the upcoming VHF contest.

Likewise, my apologies to anyone whom I've misled.

But I apologise with fingers crossed behind my back!

The IEEE Dictionary mavens have produced a very HF-centric definition of "ground wave", by defining it to include all modes of propagation except "sky wave"; where "sky" is exclusively defined as "ionospheric".

This definition completely ignores all the non-ionospheric VHF/UHF propagation modes that don't involve the ground at all.

Since a misleading definition is worse than no definition at all, the best policy for the term "ground wave" is to label it "Broken - Do Not Use".

You're absolutely right, Craig... in principle.

But Richard's situation reflects the reality for many British hams whose house is at one end of a short and narrow rear lot. With neighbors very close on all sides, we're lucky to have even one mast, so center-fed antennas are often not very practical for us - they either sag in the middle or wind up in a very sharp inverted-V configuration.

As a result, we're very much forced towards considering end-fed or base-fed solutions.

However, I wouldn't go near an end-fed long wire or zepp configuration, because of the very high risk of feeding the RF return currents into the mains. Been there, done that, had the doorbell ring!

Living in that situation myself, my best solution has been a 30-33ft vertical at the far end of the garden, fed against the best ground system I can manage. This can be fed directly on 7MHz; with an ATU at the base it is good for 10, 14 and 18MHz, and is usable on the higher bands too.

Over the years, this system has acquired an auto-ATU at the base, and has evolved into a guyed tilt-over mast with various quick-change "accessories" that can be attached at the top. A lightweight 12ft fishing pole makes a taller vertical, which has slowly crept up to 45ft; or a selection of horizontal loading wires running back towards the house at the 33ft level make inverted-L configurations for the lower bands.

With the auto-ATU, any configuration can easily be loaded on any band. It won't be optimum on more than one HF band, but it will get you on the air on *every* band - and that's what counts for most.

For a mains safety ground, the bottom line is: is the ground resistance low enough to blow a fuse in the live rail? If the answer is no, you're heading for a fire, so there is some surety in verifying that a fuse really will blow.

On the other hand, for an RF ground it's a lousy test.

The fact that you can extract only half the power from a wave with a perfectly efficient antenna is already built into Ae. That is, Ae = P/S, where P is the power delivered to a conjugate load and S is the power density of the wave.

I suspect that in your reference, Ea is the *peak*, not RMS, field strength, and that's why the factor of two.

Incidentally, while you can extract only half the power from a wave with a perfectly efficient antenna, it is possible to extract *all* the power from a wave. An anechoic chamber extracts essentially all the power from waves generated within it.

> My question is why 2Zo rather than just Zo. Is it because only half of the
power
> in the field can be extracted and delivered to a load?
>
==========

Yes. With the current induced in the receiving antenna it doubles as a radiator and re-radiates half the power back into the field. But only when the receiver and antenna are Z-matched.

If not Z-matched then more than half of the energy is re-radiated and less than half of it is accepted by the receiver.

It's a simple case of a conjugate match between a generator and a load which applies whether the antenna is resonant or not.

In series with the antenna's radiation resistance there's a small conductor loss resistance and a corresponding small loss in power efficiency. The radiation resistance changes when in an off-resonance condition and so does efficiency.

But apart from the change in efficiency, provided a conjugate match is maintained, the 50 percent receive/re-transmit condition always holds and even when well away from resonance a receiving antenna can have high efficiency.

It is required only that radiation resistance be considerably greater than conductor loss resistance. Which is rather obvious whichever way one looks at it.

Reg.

Although center-fed is not totally impossible or out of the question, you
are right, a lot of UK hams have small back lots/gardens and so many of us
do tend to seek verticals or end-fed arrangements with the feed point away
from the house. In my particular case, the problem with a vertical is that
it would practically be surrounded on all sides by either trees or the
house, so I'm not sure if going for a vertical alone would be a good idea,
and that's why I'm considering either an inverted-L or zepp or something
better.

> However, I wouldn't go near an end-fed long wire or zepp configuration,
> because of the very high risk of feeding the RF return currents into the

Noted.

> Living in that situation myself, my best solution has been a 30-33ft
> vertical at the far end of the garden, fed against the best ground
> system I can manage. This can be fed directly on 7MHz; with an ATU at
> the base it is good for 10, 14 and 18MHz, and is usable on the higher
> bands too.

Yes. Any vertical at my QTH would be about 10 metres away from the house to
the south, and about 2 metres away from tallish conifers to the north. A
vertical would seem to be hemmed in to me. No clear take of in any direction
actually.

The problem with using a center-fed arrangement, is that the most I could
put up in backgarden would be ap 40 metre doublet as per:

```
x-------------------
| \
| \
| \
| \
| \feedline
```

back garden

But the feed would be at the top of a 10 metre mast. I would have to have
the feedline go in at an angle.

So one thinks perhaps I need to end-feed as per:

```
-------------------
|
|
|
|
|
x
```

back garden

BUT, I could be daring and do this:

```
/ | \
/ | \
/ house \
```

back garden front garden

Erect a 40 dipole, feeding at point of small mast on chimney stack of house.
That means half of the antenna ends up in front garden.

Or even put up cobra:
http://www.k1jek.com/index.html
Junior does not do 160 though.

Latest thoughts:

If I could get a decent ground (and that's unknown) I bet I could do a lot worse than an inverted -L, to use for 40, 80 and 160.

Best I could do:

```
10m 10m
-----------------------------------------------
| |
| pole on house
| 10m
|
|
x feed
```

back garden front garden

Yep, might be worth a try if I can get a decent ground.

True enough on the RF , but no worse than any other test meant for primary
power. While this test alone does not insure a good RF ground and it is a
good first test to let you know you are going in the right direction. If
this test is bad for 60Hz AC then RF ground is probably a lot worse. VSWR
reading for my antenna is 1.25:1 at the resonant frequency of my antenna.
Given the inaccuracies of SWR meters I figure I have a ground resistance
some where between 3 and 10 ohms. Maybe one day I will try to to get a more
accurate reading when other things in my life take less priority.

Should re read what I write sometimes. I was refering to using the water
pipe as the sole ground for your electrical system. This used to be a common
thing and pemissable by the NEC, not sure if it still is.

When we had an electrician upgrade the incoming electrical service box on my mother's house (circa 1960), he ran a large 8 gauge wire from the box at the end of the garage, along the wall of the house all the way to the incoming water line from the street near the other end of the basement, where he tied it to ground next to the water meter.

The National Electrical Code has changed, and those in older houses might consider upgrading to current code (no pun intended) even if not actually required.

In industrial situations, I have had to deal with ground loop problems, which are a PITA to find. Do your grounding correctly, and you will be safer, and have an easier time of it.

You should have seen the problems I had when I had the house electricians wiring up an r-f shielded room. Trying to convince them that they had to run just *one* ground wire from a single point on the room to a building ground and not the service entrance ground *and* that the wire couldn't be bare and laying on the sprinkler system piping, the A/C ducts and electrical conduit in the overhead.

Then fighting off the fire department guys that insisted that they were going to run a pipe into the room for sprinklers.

Most licensed electricians (in theory all of them, but I'll leave
that) have a good understanding of issues related to DC and 60 Hz AC,
voltages up to 480, currents up to 100 A.

Once you get to higher frequencies, including RF, or to serious
voltages or currents, the number of people who really understand drops
off rather quickly, unfortunately as the potential problems and
dangers increase.

Well, Reg, your joking concerning the measuring instruments misled me. Sorry about that. But I don't call your leveling with us on your experience and accomplishments bragging. The more we know about our friends on line the greater the enhancement of our communication, even the humor will be more appreciated. I know that I'll have more appreciation of Punchinello than before.

Now, from a previous post of yours:

>Reg.

Yeah, Reg, I must have been on something pretty strong when I said that, but I can't remember what it was.

Another subject.: I'm wondering if I have your correct email address. During the past two years, or more, I've sent you several emails with no response. Yet you respond to my posts on this rraa in a cordial and friendly manner. In one of my emails I asked if I had said something that offended you so that I could apologize, but no response. During a cruise on the North and Baltic Seas two years ago I was in London at both the beginning and end of the cruise. I emailed you twice while in London and three times from the ship, asking for your phone number so I talk with you to learn how to find you for a visit.

I first used the address you show on your posts with the 'zzz', but it came back--wrong address. I then used your address without the 'zzz' with no response. Can you help me understand what went wrong, because I really wanted to

meet you while in England.

Walt

When I replaced my service in 1975, a water pipe ground (which is all my 1952 house had) wasn't sufficient to satisfy the NEC, so I had to add a ground rod. So the NEC hasn't permitted a water pipe ground as the sole ground for at least 29 years. It apparently was permissible in 1952.

Mostly an educate guess, my AC test blows a 10 amp fuse to smithereens so I figure less than 10. SWR is 1.25 to 1 This equates to about 40 ohms impedance seen at the antenna base. This also agrees with my antenna analyzer. Antenna is a full length 1/4 wl antenna on 20m. I was figuring 37 or soo for this. I know its a lot of by guess and by golly and I am aware that there are better ways of finding out what the ground loss really is but I'm not so anal that I reallly care. Given the SWR reading I figure closer to 3 and a neighbor recently had lightning rods installed and the installers measured theire ground resistance at 2.5 ohms so I am pretty confident of my educated guess .

When I get my tower up 20 meters will be on a beam on top of the tower and I plan to use the ground plane with a 40 M vetical 1/4 wave antenna. Ground plane is made of 12 wires 12ft long connected to a 10 ft ground rod at the base of the antenna. Do you think I should modify the ground plane. I was thinking of at least adding 4 wires 1/4 wl long for 40, I really think this may be a waste of time though. Also would existing ground plane be good for 80M.

Ian, G3SEK wrote:
"The IEEE Dictionary mavens have produced a very HF-cebtric definition of "ground wave"."

Regretable. Seems clear that a ground wave would require interaction with the ground. According to Terman it does. On page 803 of his 1955 edition, Terman says:

"The "ground wave" (also sometimes called surface wave) can exist when the transmitting and receiving antennas are close to the surface of the earth and are vertically polarized. This wave, supported at its lower edge by the presence of the ground, is of practical importance at broadcast and lower frequencies."

The ground wave requires the earth to participate in its propagation and the earth gives the ground wave a continuation beyond the line-of-sight without atmospheric or ionospheric intervention.

Best regards, Richard Harrison, KB5WZI

A good thing too. At any time a fully qualified plumber can come along and replace a section of metal water pipe with polyethelene, one of the best insulating materials known to science.

yeah, like they did on mine when they installed a whole house water
filter... fortunately i was watching and didn't let him throw away the handy
ground strap that came with it to jump around the filter.

I am not very familiar with USA power-grounding regulations and they probably vary from state to state. But I am under the impression that in some simple circumstances, perhaps domestic, a single ground rod is considered adequate for safety purposes.

Under similar circumstances a maximum ground electrode resistance (whatever its construction) of 50 ohms is specified.

A 'standard' ground rod is 8 feet long and 1 inch in diameter.

An average soil resistivity is 500 ohm-metres (= 2 mS). See Eznec?

The calculated resistance of a single standard rod in average soil is 194 ohms. (I'm sure the calculating formula can be found somewhere on the IEEE shelves. There ought to be greater use made of it.)

Now I don't expect the alarm bells to be rung from Washington to LA. But isn't there a serious inconsistency somewhere?

As a matter of interest, the resistances to ground of 2, 3 and 4 rods in parallel, spaced 6 feet apart in average soil, are as follows -

2 Rods = 113 ohms
3 Rods = 86 ohms
4 Rods = 70 ohms

all of which exceed the specified maximum of 50 ohms.

Quite a low average soil resistivity of about 130 ohms is needed to bring 50 percent of installations within specification.

If my starting data is wildly adrift then disregard my waffle.

Reg, G4FGQ

yeah, and its worse than that. most times they only use 1/2" or 5/8"
diameter rods, and the 6' spacing becomes 3' 'or so' when they do more than
one, which seems to be getting more common. the last electrician i hired
actually put 2 rods at a separate garage service entrance without being
prompted.... but maybe it was all the towers and other rods around that
convinced him he should do it right before i said anything.

And I had a friend, had home in Springfield Or., was built during the WAR!
Home was plummed with (If you can believe this) Electrical Conduit! Apparently,
because of the shortage of materials, this met code then! Stuff finally rotted
out, around 1971-- remember him useing his vacation to replum the house!
And I had one , in K.Falls, OR was built as old farm house, with steel pipe,
that started leaking- electrolysis was rapidly eating it- replaced with Copper.
Was curious about the UNIONS used on it-- turns out that those are INSULATED JOINTS!
Plumber said had Copper pipes eating out in as little as 3-5 years, before they were
available, with them expected 25-30 years, before the pipe gives out! As running
current thru a pipe with an insulated connection is worthless as a ground, and even
current flowing thru a copper pipe, is hazardious to its health, don't think would
recommend this tactic if you want a good ground. Jim NN7K

3050. Re: Ladder line with end fed wire

Newsgroup: rec.radio.amateur.antenna

With linear loading, you can get up a lot of wire in a small space. Take a look at
http://hamgate.sunyerie.edu/~larc/super_linear_-_loaded_inverted_v.htm for an example of a 160 meter inverted vee in a 40 foot yard!

If you want multi band operation, put up as much wire as you can and feed it with ladder line to a 1:1 balun to a short piece of coax to a tuner.

Feed it at the top so the maximum current is up high.

If an inverted L works for your lot, try feeding it at the top middle instead of the bottom end and using the linear loading technique to make each leg longer. According to Cebik if you can get 3/8s wavelength, you are very close to the full performance of a half wave. Feeding at the top middle does not require a radial field to work.

```
-----BEGIN PGP SIGNED MESSAGE-----
Hash: SHA1

My yard is adjacent to a large park. The park's border with yards
like mine consists of a chain link fence that's in excess of one
thousand feet in length. The vegetation is such that I could run a
long wire about a foot over the top of the fence for a large part of
that thousand feet. Would the chain link fence cause negative
interactions? Would this be a receive-only antenna and not any good
for transmitting? I'd connect it to the random wire lug on my MFJ
Versa Tuner II to match it to my Kenwood tube rig.

Thoughts? Comments? Suggestions?

Jack.
(I'm going to try it regardless for receiving, but what should I expect?)

|
|Apparently the electricians only knowledge of 'loop' was in 'loophole'.

Yep. To elaborate. The building (100,000 sq ft) was constructed of tip-up concrete exterior walls and steel columns and roof trusses. A few of the columns, were dedicated ground points, complete with copper plates for wire attachement. They were bonded to the steel rebar grid in the concrete slab-on-grade floor.

All of the A/C conductors into the room, neutral included, ran through some real hefty line filters that were on the outside of the room with feedthrus into a distribution box inside. On top of the room was a single copper stud for ground connection.

As I said earlier, the electricians wanted to ground the room with the usual A/C distribution safety ground wire. When I said no, they needed to go to the nearest column ground, they ran a 6 AWG bare copper wire to the grounding plate. Of course the wire was in contact with everything it contacted.

So when I saw this I said no, you have to run an insulated wire. So the next iteration was a single green wire. I said no, some bozo plumber (I shouldn't say this, my brother's a plumber) or HVAC guy will be up there working and the wire will be in the way and they'll cut it and my room with be a 100 or so V above ground due to all of the capacitors in the filters. I finally got my insulated wire in conduit.

Then the HVAC guys wanted to run a steel duct to the room. Noooo, use an insulated collar and give me a pneumatic thermostat.

Then as mentioned earlier, it was the fire department. They saw all of the handy pipes running through my feedthru panel (actually waveguide below cutoff feedthrus) and said we can just plumb in the water through one of these. Nooo, can't have a metallic connection. So they say, they can use a dielectric union. Nooo, the water in those pipes hasn't moved in 20 years and is primarily rust.

When they started talking about halon I said that my widow was going to have a real good time with the millions she would get from the lawsuit. They decided that the regular sprinkler system above the shielded room was okay afterall.

Some nice suggestions, there, especially the point about keeping the
maximum current area of the antenna as high as possible.

The antenna can be end-fed (high impedance), off-center fed (moderate
impedance) and center-fed (low impedance). With a good antenna tuner, I
don't s'pose it much matters about impedance, as long as the varying
amounts fall within the tuner's range.

It was a revelation to me to realize that a half-wave length of wire
doesn't really care where it is fed: end, off-center, or mid-point. The
high-current portion will be in the middle and the high-voltage points
will be at the ends, regardless of where the feed point is located, as
long as the wire is resonant at the operating frequency.

Linear loading is effective, but as more wire is tightly folded back
from the ends, the more narrow the 'bandwidth' becomes, limiting the
tuneable range. This would also pretty much kill the multi-band utility
of the antenna.

I use a 130-foot ladderline fed dipole, center-fed. In a location like
yours, I'd keep as much of the center portion of the antenna as high and

level as possible, and then at each far end I'd fold them down and to the side, and then back along the fence toward to the center as far as needed, clipping the wire to stand-off insulators and keeping them up out of reach of curious fingers. The radiation from the end portions is less, and is a practical compromise for 80 meters and up.

For 160 meter operation, I use "clip on" extensions that run along my perimeter fence on both sides, and they make a sort of "Z" in respect to the main antenna. This works very well, letting the center part of the dipole radiate up high, while providing enough physical wavelength to allow tuning.

All of this is a compromise, of course, but it's practical and effective.

I suspect that the performance of the "all band" antenna is somewhat less effective on 20 meters up .. but this is a much more approachable situation. I've acquired an end-fed trapped half-wave vertical for 20 thru 10 meters that is only 17 feet in length. I plan to mount it on a mast alongside the house. I suspect that the radiation pattern on 20 meters and up from this "vertical halfwave" will be much more evenly distributed and predictable than the multi-node variations of the tuneable dipole. Between the two antennas, one should be pretty well covered, given the space restrictions.

Many thanks. I do not have the space for this 4th HF antenna to get 1/2 wavelength of 2.182 mhz (214'). I can manage 1/4~ in the fashion of an inv-L antenna. A big compromise to begin with, but how would that utilize it's desired 1/4~ electrical length if I fed it anyplace but from the end? I can add radials and will have to do so if the end-fed inv-L turns out to be the best by consensus. Earth is sandy with a little clay - not very good. An MFJ-962D manual or MFJ-994 ATU, whichever performs better, and a 1:1 current balun at the feedpoint (if helpful) will be used. Estimated height of the vertical radiator from shield-grounded feedpoint to the "L" would be 37' and the remaining 70' of radiator would be horizontal. Comments on the expected efficiency of this arrangement for best performance on 2182-4125 khz are greatly appreciated. Anyone who is capable of modeling this design, that would be seriously helpful too ;-)

Yes Reg, sorry the figures are (thankfully) in error. Especially since 25ohm
is required by our U.S. NEC, and that's easily attained in some soils, not
so easy in others. This is being changed in the 2004 code changes, but it
was paraphrased below:

The NEC does not specify a maximum earth resistance for the grounding electrode system required under Article 250-81. The only place that does specify earth resistance is under Article 250-84, for "made" (rod, pipe, and plate) electrodes. Here the NEC specifies a resistance to ground of 25 Ohms or less for a single electrode. If the electrode does not meet 25 Ohms, it must be supplemented by one additional electrode. However the combination of the two electrodes does not have to meet the 25 ohm requirement!

http://www.cpccorp.com/deep.htm

Neither should anyone be overly concerned with acheiving low DC-resistivity of a grounded electrode. In spite of some interesting comments about their perceived successes in the white paper I cited above, the grounding issue is usually overstated - the ground for lightning is the real issue, as any 10' 5/8" copper rod earth ground works for 60hz electrical safety. For safe termination of lightning downconductors and mast grounds etc, the best ground you can reasonably achieve is going to be enough - as long as the principles of bonding are adhered to religiously. That means as close to equipotential as possible, and it does not assume a good ground, or even any ground at all in certain cases. We surely want the best ground reasonably attainable, and if you can sink 30' of connected rods, great. If you sink a few 8-foot 5/8" or a couple of 1"x10', even better. See the data in that paper above for some sample resistance measurements which they consider "average" (ha - Richard Clark's laughing ;-), rightfully so.

Best regards,

Jack

3057. 106.9MHz notch filter

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-10 03:50:44 UTC
From: A-Tech <atech@austin.rr.com>
Message-ID: <ow90d.7798$le.1852@fe2.texas.rr.com>
Source record: 89678

Hi,

I am a newbie here and have just dropped in to ask a single technical question.

Living as I do in a suburban area, I use an FM antenna to draw the stations located in
a certain vector from me. A station of interest is located at 107.1MHz but is interfered with by an off-axis stronger signal at 106.9MHz

The FM antenna has a "standard" 300ohm screw connection for the lead-in (to which I connect
a 300/75 xfmr and use coax down).

I would appreciate anyone's help in designing and implementing a notch filter that would suck
out a major part of the interfering energy.

It seemed to me that a reasonable attempt would be to use a piece of 300ohm flat-lead and short
it at an appropriate distance from the screw-terminals of the antenna. None of my attempts have
yielded any observable improvements. It may be that the filter must be "deeper" (higher Q?) than
what my attempts provide.

Any ideas?

Thank you.

...Bryce

Hi Bryce,

Length can be very critical as you can imagine. Trying to find the
sweet spot, over and over, can become taxing if not simply fruitless
(undoubtedly your experience to this point).

A simple method is to connect the twin lead in the usual manner.
Measure out a little more than 1.5M to work with (this will be too
long, but it is better than being too short). Take a razor blade (old
style used for scraping paint) and working from the far end cut
through the insulation of both leads at once to short them out.
Repeat at 1/16" intervals (or 1mm intervals if we are sticking with
metric) and note results. You don't want to cut through completely,
just enough to nick the copper and make a good short with the blade.

Keep in mind that while you are handling the line doing this, you are
part of the tuned circuit (and possibly detuned circuit too). It will
give you a quick ball-park and reduce the cut-and-try.

Unfortunately, you will find that the -3dB BW of a single stub is in the
neighborhood of 5% or >5MHz at your frequency of interest. The
discrimination between your desired and undsired channels will be
negligible.
We manufacture a line of small multiple cavity symmetrical and asymmetrical

notch filters- getting under 0.5% BW with small topology filters is nearly impossible at VHF.

Hi Jack,

Interesting link.

The paper offered was a model of terse reporting, sticking only with
the facts as best they could come by them, and little in the way of
overextending themselves with fanciful interpretations. The averages
were what they found for themselves, not abstracted and generalized to
the world at large.

I would suggest that they also made some cogent observations about the
soil structure that goes beyond myths and software passing as the new
age equivalent of old wive's tales. I would further observe that
making a declaration of what the resistance of ONE electrode is, is
farcical in the extreme. It would take two to tango and with that
second one added to measure the first, problems abound!

Especially notable is the 10 fold variation in reported electrode
resistance over a 4 year period, and the 10 fold variation of
electrode resistance within a survey group. Such an error range
easily eclipses what is taken on faith as "average ground." And then
we have to ask ourselves that embarrassing question, just how does the
mud in my backyard compare to "average?"

Your comments on
>That means as close to
>equipotential as possible, and it does not assume a good ground, or even any
>ground at all in certain cases.
translate with fungible results to RF for the same reason. No one
here knows what quality ground they live over (really! to one skin
depth at HF?).

I would still like to know how many radials Reggie needs for his
several KOhm mud in his garden. No, I take that back, what I want to
know is what parameters he puts into the software that predicts the
number of radials - and why would it matter?

I agree with Dale that you're not going to get anywhere near sharp enough a filter by making something out of twinlead. Since the signals are coming from different directions, it might be more practical to make a null in the antenna pattern in the direction of the interfering signal. This is most likely to work if the desired station is reasonably strong, so it doesn't have to be in the direction of the antenna's maximum response. A two element phased array can be designed to achieve a deep and fairly narrow null, and you get a deep null off the end of a very symmetrical dipole or the side of a Yagi. If the directions are fairly close, an antenna with wider beam, like a 2-element phased cardiod pattern array or a dipole, would give you more of the desired signal when the undesired one is in the null, than a Yagi would.

You might have to use some sort of feedline decoupling (common mode choke, also known as a "current" or "choke" balun) to prevent the feedline from being part of the antenna and reducing the depth of the pattern null.

they 'why' is the real question as there are several reasons to design a 'ground' and each of them has different requirements. a few examples with different needs:
1. home electrical safety ground.
2. electrical substation ground.
3. hv transmission line ground for step or touch potential.
4. hv transmission line ground for lightning protection.
5. building ground for lightning protection.
6. building ground for rf isolation
7. vertical antenna ground for rf return
these are all very different problems requiring very different solutions. i write software, part of which helps design grounds for hv transmission line structures. the theory and practice in this area is quite different from that used to design any of the other types (except maybe for small buildings requiring lightning protection). And some of the extensive testing we have done on the physics of the problem shows that the ground reacts quite differently from what most people expect when trying to dissipate lightning transients. i wouldn't use my software to design a ground for my station, though i did use some of the results of our tests to convince myself that what i did do would be adequate. Nor would i take any one other program as gospel when designing a ground for any particular type of installation. indeed at my station i have several different types of 'ground' systems, raised radials under elevated verticals, wire mesh mats on the ground under elevated verticals, ground rods at towers and service entrances, ufer grounds in foundations, perimeter ground around the house, each for a slightly different purpose and no one good enough for all the jobs that need to be done. Some help with rf radiation from antennas, some are lightning protection, and some are for ac safety. and they can't be interchanged in most cases... and some of them would not fit most layman's definition of what a 'ground' even is.

i would also expect it to be rather poor for transmitting though it might make a decent low band receiving antenna similar to a Beverage or wave antenna. its one of those situations where i would recommend that you 'plug it in and try it', you might be surprised at how well it works, or you might have trouble getting around the block.

You could also put the filter not at the antenna, but back on the lead in just before the receiver. That way any 106.9 being pick up in the feed line are also attenuated.

Have you tried calling the 106.9 station? Years back, many stations freely (or very cheaply) provided filters to people experiencing interference from their signal. I remember back in 1987 I had a customer whose Muzak SCA reception was being trashed from a nearby broadcaster. I was expecting to pay for a filter, but the station engineer literally left one at their reception desk for pickup.

I would not expect free, but you could hope for inexpensive. Never hurts to call.

Good luck,
B.

A "too short" dipole has a feedpoint resistance lower than 50 ohms.
Why would one use a 4:1 balun to attempt to divide that already too
low resistance by 4?

Source record: 89687

Two big advantages of the center top feed as opposed to bottom end feed is center top requires no radials. Bottom L will need a minimum of 8 100 foot radials in your application and some would argue you need many more than 8. Have fun burying 800+ feet of wire. Second, top feed gets the high current radiating part of the antenna up higher. Check out http://www.cebik.com/ltv.html and his discussion of ladder line at http://www.cebik.com/gup/gup32.html. He concludes a 1:1 balun is best.

If you have 37 feet of height you can feed at the top and run the wire straight down, back up and then down again for a total of 3x37= 111 feet of wire on the vertical side. On the horizontal just bend back at the end or let the end drop down vertically. Sure it will have narrower bandwidth than a straight dipole but you have a tuner and you can't have a straight dipole.

"sky wave - a radio wave propagated obliquely toward, and returned from,
the ionosphere."

Apparently, if it's not returned from the ionosphere, it's not a
sky wave. That implies that the stars are not in the sky. :-)

On 40m, 80m, and 160m, it would act more like an inverted-L
with lots of feedline radiation. On those bands, you might
as well put up an inverted-L.

On 20m, it would have a very high feedpoint impedance in the
neighborhood of thousands of ohms. The feedpoint current is
pretty low so the current unbalance has a limit. For 100w, the
feedpoint current would be about 0.15a. Of course, the feedpoint
current in the other wire is zero since it is floating at the
antenna feedpoint.

On 40m, it would have a very low feedpoint impedance in the
neighborhood of 40 ohms. For 100w, the feedpoint current
would be about 1.5a, a magnitude more current unbalance
than the 20m case.

Hello,

Firstly what does "Q" stand for?

You could try and shield the antenna from the other transmitter depending on where everything is located. You might be better buying a decent tuner with a narrower filter built in, often Kenwood or Sony have this feature. I have a DENON and it suffers from the same problem of having WIDE filters so it can't select individual stations too well without getting hammered by the one next door.

3070. AH-4 Tuner and Attic Wire, Comments Please

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-10 13:10:16 UTC
From: Tom S <nobody@home.com>
Message-ID: <chs80r$gq9$1@avnika.corp.mot.com>
Source record: 89691

My current attic situation consists of a 20M dipole, a 30M and two 40M MicroVerts, and an 80M Hamstick Dipole. Using a homebrew antenna switch, I can switch between all these and use a tuner in the shack to make everything look good.

I was thinking of doing the following and am looking for opinions/sugestions/comments both good and bad.

I would remove all the stuff above and run ~100 ft of 14G insulated solid copper house wire around the perimeter of the attic. Use the control cable for the switch to run a Icom AH-4 auto-tuner connected to the wire. The wire will be run in "T" figure (I'll forgo the ascii art). Basically; West ~15', North 15', East 10', North 15', East 10', South 15', East 10', South 15', and back West near the start of the run. I only have access to the metal conduit runs on the attic for ground.

This is the setup I had, along with a homebrew balun to feed the coax) for my SWL days and it worked pretty well. I pulled the wire down when I put all the other stuff up there but can re-install in any configuration available. The longest straight run I can make is ~ 35' diagonally. Woulkd I be better off just running a straight piece rather then all the ziggin' and zaggin'?? How about putting it up as a big "Z" (25' West, 35' diagonally NE, then 20' East)??

Any inputs on this plan are appreciated befor I spend the $$ on the tuner.

Thanks,

Tom - AC9TS

Described the radials once but that text has been snipped.

12 12f t wires, Center ground stake 10 ft long, far end of each wire has a
stake about 3 ft long. These are used more to just hold the wires in place.

Hi Craig, Mr. Cebik says nothing about wrapping radiators back and forth
near each other as the earlier referenced url:
http://hamgate.sunyerie.edu/~larc/super_linear_-_loaded_inverted_v.htm

Cebik does comment:
"Bending the horizontal arm far end down: If horizontal space is limited, a
common practice is to bend (or dangle) the outer ends of a dipole downward.
since the region is the high voltage and low current portion of the antenna,
the radiation pattern is least affected by modifying the geometry." -and-

"Like many wire antennas, the inverted-L will tolerate moderate alterations
of geometry to fit the space available and still yield good, if not peak,
performance."

> >> > each leg longer. According to Cebik if you can get 3/8s wavelength,
> >> > you
> > are
> >> > very close to the full performance of a half wave. Feeding at the
top
> >> > middle does not require a radial field to work.

It doesn't appear that Cebik intended to imply that 3/8~ off-center feed
would ever approach true1/2~ dipole performance, just that it would still

operate. These off-center-fed variations (of Carolina Windhams?) are confusing, no matter how much wire they use. Remember I don't need an all-band compromising performer like the T2FD or Windham, but a specific performer on 2182 Khz, and hopefully at least through 4125 Khz. Doing this with 70' of horizontal span and two vertical attachment points about 37' high is the challenge I am asking for help with. I cannot run anything like KG�ZP does, which creates (in his location) a near-field coupling nightmare, in my opinion. Your suggestion (doubling the verticals), which varies from both the KG�ZP design and Cebik's "moderate geomtery alterations", would at least add electrical length, but it remains off-center-fed and therefore never creates a 1/2~ dipole, correct?

If I stuck with a 1/4~ end-fed L, and only used 8 radials of 20-40', could this still outperform an off-center-fed antenna off any length on 2182 Khz?

Thanks again for the comments and ideas,

Jack painter

Many years back, either Radio Electronics or Radio and TV news published a how-to article which described using two
identical Yagis horizontally "stacked" and gave formulas or charts to determine the spacing for creating an off axis
notch to do what Bryce needs to do. Otherwise, either Dale's filters or some from an outfit named Eagle may be the only
answer.

All the individual "loose" connections at the joints are notorious for creating intermod. It may or may not be a
problem in your case. For receiving, you may hear numerous broadcast station harmonics and intermod combinations. When
transmitting, your signal will likely be "dirty" and you may get BCI and TVI complaints, even though your transmitter is
clean. Sort of like putting a thousand diodes in the antenna.

I think, as Roy suggested, that your best attack will be to aim
the antenna to provide the deepest null to the "... off-axis
stronger signal at 106.9MHz". Peaking the desired signal is
only a secondary goal here.

Don't spend a lot of Big Bucks trying to solve this problem.
Marvin's Law (Murphy's brother) says that once you _have_ put
considerable money, effort, and time into this, the station's
(new) owner will change the format to Country or Jesus.
(Now, How's *that* for provoking thread drift?)

Hi Jack,

Are you anticipating an emergency? (perhaps a stupid question given
the flurry of Hurricanes) I presume you are interested in listening;
and if so, you won't find any remarkable variation in signal strength
across a wide spectrum of antenna styles (ï¿½50% in bulk wire
differentials) and/or topologies.

Hello Bryce,

I'm sure you're aware that these two frequencies are adjacent channels. The FCC allocated channels such that adjacent channels stations would not be located in the same geographical area, expressly fo the purpose of preventing such interference. Obviously the two channels involved are not in the same area, and it seems strange to me that you can even hear the station on 107.1 MHz.

I believe that your only hope is to orient your antenna to place the null in the direction of the 106.9 station, as Roy suggested,, but I'm not sure that even that will reduce the 106.9 station sufficiently to allow acceptable reception of the 107.1 station. In addition, I firmly believe that attempting to filter out an adjacent channel will be futile, and not worth the effort.

==========

Jimmie, For amusement and my education, would you mind letting us have a few more crude details of your ground radial system please.

TYPE OF SOIL

(A) Is it high quality, fertilised garden loam, perhaps very slightly sandy which can grow flowers and shrubs of which you can be proud when you try. Perhaps used to be farm or orchard or agricultural land.

(B) Is it slightly gritty, stoney, but ample body which can still make a nice flower garden. Quite fertile even though it may be overgrown with profuse, dense, robust weeds. (Like mine.)

(C) Is it sandy, clayey, with small stones or pebbles? Needs attention with fertilisers to grow nice flowers. But a lawn might do very well.

(D) Does it contain stones, sand, grit and small rocks with only 75% of good soil but still needs hoeing and weeding to keep looking presentable.?

(E) Is it poor soil, smewhat infertile, difficult to manage as a flower garden? Could be turned into a rock garden. Even the weeds don't do very well.

(F) Thin layer of mediocre soil over bedrock.

MOISTURE CONTENT

(G) Fairly wet.
(H) Nicely moist.
(I) Slightly damp.
(J) Well drained, dry.
(K) Dusty.
(L) Arid.

ROUGH DEPTH OF WIRE BURIAL.

In tenths of an inch if very shallow.
Zero if just trodden in, in good contact with soil surface.

Thank you.

Reg.

Hi Richard,

The 2182-4125 Khz USB antenna reqirement is for transmit and receive operation from a USCG Auxiliary radio facility. I agree the reception of 2182 across all of my HF antennas is about the same, typically copying stations 500+miles away in the summer, and certainly better at night, and in winter. But I need to improve transmit capability to a reliable 200 miles minimum. And yes, we do get grazed often and ocassionally hit by hurricanes here. ;-)

Message-ID: <chsrimrol1@newshost.mot.com>
Source record: 89704

The connections don't have to be diodes at all to cause trouble. Although that is one possibility, there's another effect.

The fence will have RF current induced in the conductors - posts, rails and links. These currents can come from any transmitter. After all, it is just like any other antenna, except that it isn't connected to a receiver. Any and all conductors that exist are picking up RF currents just like the ones we call antennas. There's nothing special about those conductors we call antennas (in this regard). It is why the Yagi works.
Where two conductors touch, you may or may not have current through the joint depending upon the RF field. As these conductors make and break contact, lets say in the wind, the current through these connections will also most certainly change. This changes the current in the conductors and since these currents cause some small amount of radiation, the resulting radiated field will change also. Because your antenna is near to these unintended elements and can pick up a significant amount of signal from them, two effects can result.

1- When you receive, this can cause noise in your receiver. What kind of noise? The easiest to understand would be if you have a local radio or TV station. The currents caused by this station can be rather high and therefore significant. Becuase the field in close proximity to this "dirty" antenna is changing in a noisy manner (described above), due to the bad connections, the signal as seen from this transmitter is also dirty, or noisy. It looks just like modulation, noise modulation extending, in the two sidebands, away from the carrier. To a receiver this looks just like noise modulation on the transmitter.
The bandwidth of this kind of noise can be rather startling. A 10 MHz transmitter can have noise easily extending up into the GHz region. If the field from the transmitter is strong enough, the noise can cover what you are trying to recieve. I had to troubleshoot this problem at 150 MHz once. This can be duplicated by listening slightly off channel of a signel. A 2M repeater will do. Just go 5 or 10 KHz. If you are very close, you may be able to tune further off. Now just take any two conductors of a few inches or more in size and rub them together within a few inches / feet of you receving antenna. I call this "the screwdriver effect" because I first saw it when a screwdriver was drawn across a chassis & I heard noise.

2- On transmitting, you have the same situation, except YOU are the close transmitter and your signal can have this noise modulation. I lied. Its the same effect.

On calm days, perhaps you'll be ok.... perhaps even on windy days. RF is fickle.

On the Program Apollo ocean ships used for monitoring communications around the globe and spacecraft recovery, chain used on parts of the deck railings was found to be the source of noise which modulated the multi-Kw HF transmitters resulting in degraded Radar performance! I think it initially made the radar useless.

When you are BETWEEN markets, this is common. Or, if you want to listen
to a distant station and the wrong one is close. I'm equi-distant from
Chicago, Milwaukee and Rockford and have this problem hearing WDCB 90.9,
west of CHi-town with WHAD 90.7, S-W of Milwaukee pounding in. They're in
different markets.

This was discussed not to long ago here. A notch in the antenna pattern
is not too difficult. Two vertical dipoles spaced (about) a half wave and
fed with the proper feed line so they are 180 degrees out from each other,
can make a nice null - actually two. They are perpendicular to the plane of
the antennas. I'd have to sit and tinker to remember the feed system, but
there has to be 1/2 wave more feed line in one dipole, compared to the
other.
It is also possible to do the same thing and get a one notch pattern
(cardioid). If I recall, the antennas are spaced 1/4 wave apart and the
feed is 3/4 wave of feed line between them. Again, the receiver simply
connects to one of them and the null is off one end.

> Any inputs on this plan are appreciated befor I spend the $$ on the tuner.
> Thanks, Tom - AC9TS

I'd go for the long run or perhaps a 90 degree "L" using the two longest
possible lengths.

35' is close to a 1/2 wave on 20 and 2 halves on 10 making it harder to
match (high Z) on those bands. It's nice to keep your antenna away from an
even number of half waves so the impedance isn't too high.

HOWEVER, using the conduit for "ground" means that IT WILL BE part of the
antenna. It will probably be near the antenna. Not good.
It is anther random variable. Not good.

Not being "good" doesn't stop many of us. SO...RF is fickle...try it.

Richard, towers are courtesy of Virginia Loblolly Pine! They run all the way into the heavens, attract lightning like nobody's business, and pretty much ruin homes when they come down in hurricanes or Nor'Easter's. But they are also god-given antenna towers offering large limbs starting at about 50' on up. I try to use the lower parts of the trees (50') so as to reduce sway. From a 3' dia tree there is none, the more slender sky-cranes move a lot.

```
| |
-0- ------------------------------------0-
| |

-- --
| |
^ |----- / /------|
| | |
50' | |
| |
| |
------------ 70' ----------------
```

Basically, I have similar arrangements for 5 & 8mhz dipole, longwire, random wire, etc.

Jack

3088. 160 thru 20 meter homebrew vertical system

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-10 21:49:13 UTC
From: denton <denton@oregontrail.net>
Message-ID: <10k48almvc5ui2e@corp.supernews.com>
Source record: 89709

Hi all...
I am starting to work on something to use on 160 thru 20 meters.
I currently have an aluminum mast that is 32 ft long with a small cap hat on top.
the antenna will sit in the center of an area approx 50 z 50' (backyard). I plan to put down 40 plus radials, the majority which will be situated to radiate out from the base of the vertical.
some will meander along the house foundation and property line..
I plan on also tying in the galvanized (not chain link) fence around the back yard to the radial system, as well as the house plumbing.
40 meters should be direct feed.
I will homebrew a matching L network for use on 160 thru 60 meters.
I will also try a 20 meter tuning stubb.
Does anyone know what the size of the loading coil that MFJ uses in their 80 & 40 meter vertical?
I have read of just about everything I can find online of this sort of project and have played with Eznec demo a bit and think this will be a doable project.

Leave the old antennas up there. That makes it easy and fun to make comparisons
to see how well your new antenna does as compared to the old.

>and run ~100 ft of 14G insulated solid
>copper house wire around the perimeter of the attic...

This sounds like you almost have a loop. You might consider trying a random
length loop around the perimeter edge of the roof. one big advantage is that it
requires no ground with which to work against. I have about 200' of wire in mine
which peaks at about 20' up. I feed mine with ladder line, but for short runs
coax is ok as the loss would be small. I lucked out because by using a 4:1 balun
it turned out that my TS870's internal tuner is happy with it on all HF bands
except 80 and 160. For those bands an external tuner works fine. It's no DX
antenna, but I never have any trouble making or finishing QSOs. And compared to
my 40M Hamstick attic dipole, the loop gets on average about a 2 s-unit better
report.

Yeah, Steve, but isn't FM broadcast wirh horizontal polarfization? With vertical
dipoles the only signal you'll receive is from reflect;ions off objects such as
buildings. What kind of reflection coefficient would one expect ? Enough for a
good signal?

Walt

Hi Jack,

I usually lurk here quietly, but thought
I'd stick my neck out.

I just did a quick analysis on EZNEC.
Imagine a wire that is 50 feet up, 70
feet across the top, hanging down 40
feet on each end for a total of 150 feet.
Feed it in the center of the top with
75 feet of 450 ohm line.

The impedance seen at the end of 75
feet of 450 ohm feedline looked pretty
workable on both 2182 and 4125 kHz.
(Yes, you need an antenna tuner, but
it could be very simple for just two
frequencies.) An NVIS antenna like
this is great for short range (a few
hundred miles).

Download the demo version of EZNEC
from www.eznec.com . It'll take you a
couple of hours to get familiar with it,
but then you can play "what if" with
a lot of simple antennas like this.

>Does anyone know what the size of the loading coil that MFJ uses in their 80
>& 40 meter vertical?

Dentron, The size of the loading coil is not so important as the inductance
of the coil.
What I would advise is put the best ground radial system you can. Beg,
Borrow or Steal an antenna analyzer and determine the impedance of the vertical
at the frequencies you wish to work.
Then use the Smith Chart, to determine what L network configuration will
provide a match.

Source record: 89717

{original msg at end}
Firstly, let me thank you one and all for your responses!!

Also, I did not clearly define the antenna which is a
multi-element yagi of Winegard design - a "standard"
consumer product - and roof mounted.

In addition, I have MapQuested
the two transmitters and find that the interfering
radiation comes from behind, about 25degrees
off axis. This signal originates about 30miles behind
me and the desired signal is about 55miles in front.

Richard Clark took me along the method that I had
tried - and that I have had no success with.

Dale W4OP points out that this type filter,
at these frequencies, have almost no effect - boo!

Roy Lewallen, W7EL, concurred with Dale and suggested
a "phased array" design. Unfortunately, this is beyond
my capabilities. Roy and Walt, W2DU, both agreed that
using "null tuning" might help. Roy also suggested a "choke"
for the feedline to reduce feedline pickup. - But it seems to me
that 95% shielded 75ohm coax should not be a
contributing factor.

Bob suggested that I call the offending station - I did that
but I have to wait until Monday to speak with their
engineer - boo.

Crazy George alluded to an article about constructing
a "stacked yagi" - interesting and within reasonable
economics - but no details or source for details. Ah well.
He also brought back into my memory EagleFilters
which I have used in a cable television distribution
setting. I'm looking them up on the Internet now.

"jqo" suggested shielding from the bad signal, a strategy
I have successfully used in C-Band-satellite-receiving-antenna
placements but....on my rooftop? Also, he suggested a tuner
with better selectivity. I agree and am on eBay looking for
a better unit than the Cadet AM/FM Radio card that is
installed in my PC and connected to the outdoor antenna.

BTW, "jqo", Q, in a filter, means "quality" but is really a
figure of merit that refers to width of the 3db down points

(in frequency) and the total energy removed. High Q filters
have narrow -3db points and suck out LOTS of energy.

Jonesy suggests that if I just wait, like the weather, the station
will change format and I'll no longer care to solve this!!

Thanks all - any additional comments are most welcome.

...Bryce

Thank you very much John. I admit not giving two hours of learning time to my EZNEC demo, but I wrote it off as too complicated to assimilate in the time I could spend on it. That's an interesting finding on a "short" dipole tuning up on 2182. I had not considered what ladderline to a dipole might allow...

With the added knowledge of your antenna and your technical capabilities, the approach I'd encourage you to try is to simply turn your antenna while listening. It might not take much turning to get the interfering signal into a null, leaving the desired signal close enough to the peak of the front directional lobe to be strong enough.

The problem with feedline pickup has nothing to do with the shielding, it's caused by current on the outside of the shield. But it's not likely to be a concern with your commercial antenna and coax because of the way these antennas are typically fed.

A company in FL - well, they might have been blown away by now - called
something like Pizio Technologies makes VHF bandpass filters from "crystal"
elements. Such filters are capable of rejecting adjacent channels in the
150 MHz range and are needed in some cities if you have to put a receiver
downtown.
As Dale points out, it takes a serious filter indeed to perform what you
wish such a filter to perform. On the other hand, I have deliberately tuned
some higher end FM broadcast receivers to a weak adjacent station in the
presence of a fairly strong station to find a bit better than mediocre
performance. Some receivers have much better filtering than other
receivers.
So, as another summery: rotate antenna for best SNR; get a receiver
with better filtering; and consider a special-made crystal filter if you
still have a problem. 73 Mac N8TT

First shield-ground the feedline(s) to an external ground at a bulkhead or under-house or next-to-station ground rod. Then:

Take a bulkhead SO-239 connector; screw and solder it to a copper or brass bar so that the center of the connector is filled with solder thru a 1/4" hole from the back. File smooth. Bond that bar to your RF/safety ground system (that nearby ground rod), and before a storm approaches, short the feedline(s) to this ground source. I've gotta add that before you short feedlines to a ground connection *inside* your shack, be sure you have all equipment cases bonded to that ground source via independent single-point connections to that same source, unplug all the equipment from AC power sources, and stay away from the equipment during a thunderstorm!

Source record: 89628

Most of the info I got on linear loading comes from ON4UN's book Low Band Dxing. It is a great source.

The top fed L I am describing is center fed. There is an equal amount of wire on each side of the center insulator.

I just find this solution a whole lot easier than burying 800 feet of wire to make a bottom fed inverted L.

Try a receiver with decent IF filters. Unfortunately, this might be
hard to do in this day and age, but at one time companies
were using crystal filters in the IF stages that offered some
decent adjacent channel rejection.

I will be taking the ARRL course

http://www.arrl.org/cce/courses.html#ec004

starting Oct. 1, 2004.

The course outline mentions the use of EZNEC 3.0 or NEC-Win or "or that you are willing to adapt the ideas that we shall explore to the package available to you."

Has anyone taken this course using 4NEC2 by Arie?

Is it reasonable to take this course using software other than that recommended?

Thanks.

Thomas

If you can master the basic use of 4nec2 I don't think you'll have any trouble translating the exercises in the course to Arie's excellent program. I enjoyed using 4nec2 with the course, but a friend who is not as computer savvy had a hard time learning 4nec2 and finally gave up and purchased EZNEC.

Soil is kind of a strang brew. when the house was built there was quite a hill here that was leveled off. When the top soil was put back they put down the top soil with about a foot of clay over it. So I have a foot of clay a foot or so of top soil and more clay. Top layer of clay can get faily dry while the layer of topsoil and underlying clay stay fairly moist. Grass and trees grow fairl well and I never have to water them. Sometimes the grass browns when we have drought conditions but the fruit trees always seem to do well. I susppect this is because they can reach the underlying moisture.

I should add other than phased stacked antennas to null
the unwanted station, there is really no practical filter you
can use to notch an adjacent FM channel. A custom
crystal filter might do it, but that's many hundreds of
dollars. It's far easier and cheaper to do this sort of
filtering at the first IF. It might be easier to retrofit the
receiver with a good IF filter as compared to trying to
notch the undesired signal or bandpass the desired
signals at the operating frequencies.

Jack,
It's certainly worth a try as a receiving antenna. Using it to transmit will probably be a different story altogether! Along with all the other comments, just remember that those fences probably get very close to your neighbor's houses (and electonic devices). You wouldn't believe the complaints I got when doing something simular! LOL

Hi Jimmie,

My last post responding to this included a mistaken analysis. I had
picked up the sample vertical and did not notice it was using MININEC
ground, which is unsuitable for this question.

On using the particulars you supply above, the results are very much
different.

With the default ground (0.005/13):
Impedance = 57.96 + J 0.1116 ohms

With extremely poor ground (0.001/3):
Impedance = 65.24 - J 0.1441 ohms
SWR (50 ohm system) = 1.305

With poor ground (0.002/13):
Impedance = 55.64 + J 0.1153 ohms
SWR (50 ohm system) = 1.113

With "Pastoral" ground (0.01/14)
Impedance = 56.62 + J 0.1475 ohms
SWR (50 ohm system) = 1.132

With very good ground (0.0303/20)
Impedance = 54.38 + J 0.3596 ohms
SWR (50 ohm system) = 1.088

For each change of ground I drove out reactance by trimming the
radiatior to

You can check the Wireman's spark plug apparatus for balanced line at
http://thewireman.com/ground.html#878
or do what I do -- just disconnect the line outside the window with
banana plugs when the sky gets dark.

Hi Jimmie,

My last post responding to this included a mistaken analysis. However,
it has been now thrice plagued. Originally I had picked up the sample
vertical and did not notice it was using MININEC ground, which is
unsuitable for this question. Then in doing the suite of grounds, I
had truncated the radials by half in a frequency translation. Then I
fumbled the wrong key -sigh-

On using the particulars you supply above, the results offer the low
end of ground resistance by your estimate. However this depends on
several things (not surprisingly - ground). Does your analyzer read
real resistance, or simply SWR? What does it read with a 50 Ohm
resistor (taking the average of several, all with close trimmed
leads)?

Anyway, by your SWR reading it appears your situation corresponds to
an "extremely poor ground." Curious thing about the nature of
"extremely poor," is that what does this mean? There is every
indication that it offers the least loss, and yet it also offers the
poorest signal out (at 10ï¿½ as an indicator of DX).

With extremely poor ground (0.001/3 Zground = 209 Ohms):
Impedance = 39.46 + J 0.234 Ohms
SWR (50 ohm system) = 1.267
-6.01 dBi @ 10ï¿½

With poor ground (0.002/13 Zground = 104 Ohms):
Impedance = 42.34 + J 0.1014 Ohms
SWR (50 ohm system) = 1.181
-3.25 dBi @ 10ï¿½

With the default ground (0.005/13 Zground = 99 Ohms):
Impedance = 43.64 + J 0.03538 Ohms
SWR (50 ohm system) = 1.146
-3.36 dBi @ 10ï¿½

With "Pastoral" ground (0.01/14 Zground = 87 Ohms)
Impedance = 44.93 + J 0.515 Ohms
SWR (50 ohm system) = 1.113
-3.00 dBi @ 10ï¿½

With very good ground (0.0303/20 Zground = 57 Ohms):
Impedance = 44.5 + J 0.3779 Ohms
SWR (50 ohm system) = 1.124
-1.11 dBi @ 10ï¿½

For each change of ground I drove out reactance to less than one Ohm
by trimming the radiator to what you describe as a full size
quarterwave antenna.

Going back to the nature of ground, we return to the descriptions of
conductivity and how a "very good" conducting soil is NOT what you
want nearby in terms of matching. A "very good" conducting soil is
injecting several ohms more resistance into your feed than an
"extremely poor" quality soil. However, when we consider the Z of
ground, we observe that it is the ratio of this impedance to the ï¿½ther
that is the better indicator of achieving good low angle launch
characteristics. Consistent here are the SWR of 6.6 for "very good"
soil compared to the SWR of 1.8 for "extremely poor" soil.

There is less conductive loss (but more capture of power) in the
"extremely poor" soil and there is more conductive loss (but less
capture of power) in the "very good" soil. Clearly it is the
REFLECTIVE attributes of the media interface that is the more
compelling characteristic than with the so-called boon of
conductivity.

Two more points of practical consideration here:
1. With 12 radials laid out as you have, there is very little
variation over "average" grounds (no point in trying harder);
2. The DX angle is driven by ground characteristics many wavelengths
out (no point in worrying about ground either way).

My dear Walt,

I have so many messages on my screen that some are being displayed as "no longer available". Fortuately I did find your appeal amongst them. Anyway, I shall now delete the lot and start again with a clean slate.

Over the years I have been aware of some of your communications. On one occasion I received a parcel of your papers, which I think you also sent to other people, for which, if I remember correctly, I briefly thanked you for.

On another occasion you said you would be visiting Europe and it would be possible for you to visit me. Not being the best of sociable people (an admitted personal handicap) and not being in the best of health to receive visitors at the time I'm sorry I did not take the possibility sufficiently seriously.

I am still not in the best of health and never will be. On the other hand I do not expect to pass into the next world in the immediate future. Its just old age. But I still have my wits about me.

And I can express myself well in plain old English without having to revert to the subject of Boston Tea Parties. And beginning a sentence with 'and' is perfectly legitimate.

So Walt, what's on your mind? If you would like to discuss things in public it's OK by me.

What about "The Conjugate Match".

(Believe me, it took several minutes to recollect the name of what sort of match it is. But perhaps that's because I'm 3 parts of the way down down a bottle of European Rumanian Red. I hasten to add I have no intention of neglecting the excellent Californian varieties.)

Yours sincerely, Reg, G4FGQ

3125. Newbie question about FM aerial and portable radio

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-11 21:33:29 UTC
From: Ger <gerdalt999@hotmail.com>
Message-ID: <5aK0d.27063$Z14.9247@news.indigo.ie>
Source record: 89646

Apologies in advance but this seems like a real dumb question.
I have cable TV and with it cable FM radio in my home.
I listen to FM radio on my home stereo unit with the FM coax radio signal plugged in the back!
Perfect reception.
Now, I am the proud new owner of a kitchen type portable FM radio receiver.
But the portable has no aerial co-ax socket at the back - just rabbit ears.
Is there any way I can get quality FM reception on the portable using my cable coax connection?
I am prepared to take the back off and do some soldering!!
In hope
Ger

3126. Supporting 450 ohm feeders across an open area

Newsgroup: rec.radio.amateur.antenna

I am looking for a way to run 450 ohm wire to a tower approximately 50 feet away from the shack. The tower is only 32 feet high, but I plan on doing one of Cebik's (or is it Cecil's) rotatable 44 foot dipoles fed with open wire feeders. I'm wondering what some of you have done to support a run of open wire feeders to stop it from flopping in the wind. Thread some rope through the windows of the feed line? Thanks.

Well, Reg, what has been on my mind for a long time is whether I was getting to you with the correct email address. It's gratifying to learn that I have.

I am indeed sorry to learn of your disability, and understand why visitors would cause you discomfort. However, if on chance I'm able to visit your marvelous UK again I'll at least call you on the phone. I must tell you that Peter, G3WIX answered my post, and gave me your number, which I'll be sure to have with me.

My regret while in the UK is that the time was too short, because I would have liked to see more of it than one day in London. I'd lke to avoid Heathow next time, though. Took a taxi two hours get out of it. There are several other UK hams that I'd like to see. In addition, my ancestors blew in from Scotland in the late 1700's, so I'd like to go to Glasgow and research to see how far I can go back.

I'll need to refresh my knowledge of the location of JC Maxwell's museum (think it's Edinburgh) to go there and see his ancestral line to determine if any of his parallel mine. Wouldn't it be neat if I could say a micro amount of his knowledge rubbed off on me?

So Reg, just when you least expect it, you may get a jingle from me sometime. I'll be sure to have a goblet of the appropriate spirits in hand that we can clink when I call.

Walt

Hi Ger,

Go to radioshack and get a 300 Ohm to 75 Ohm TV adapter. The 300 Ohm
side is with the free leads. Cut off the leads and replace with
alligator clips. Connect clips to FM antenna rabbit ears (I presume
you were literal with their being two) and connect a standard cable
between the adapter and a cable outlet.

Terry,
Ever seen the 'ribbon' type banners? When you do, you'll notice they are twisted to
form sort of a spiral. Part of the reason is because the 'spiral' sort of averages the
ribbon's cross-area over a long span. Do the same with your ladder line, twist it. It'll
still flop around a little but nothing like a straight run of it will.
How to support it over a 50 foot span? Depending on the size of conductors used,
it ought to support it's self. There's no real need for large conductors, either. A #18
hard drawn copper wire will support much more than it's own weight. Shouldn't be a
problem unless you hhappen to get some very high winds...

If done like Chaska MN, it would be using 1 watt 802.11G transmitters
with 6 dBd vertically polarized antennas. The system is a mesh network
fed from relatively few points. These systems transmit only when
traffic needs to be passed. The density varies from about 8 to 20
transmitters per square mile from what I've been told by the city.

I have heard of no complaints from weak signal 1296 users in the area,
and I am a member of the local VHF/UHF/uwave club.

Source record: 89654

I know this is amateur group but I thought you guys will have some answer.
Got a unused TV yagi antenna with about 12 directors, dipole, and a reflector.
Want to hook up a 300 ohm cable to my Sony 2010 receiver FM input. Do I need to
hook up a balun? If yes, would a 75 ohm be good enough? OR should I just forget
about this plan? TIA.

3134. Re: Yagi antenna for FM/AIR reception

Source record: 89655

Depending on the antenna it will work well or not so well, but still may
cover VHF aircraft. A 300 to 75 balun should be fine, assuming the
antenna uses a 300 ohm balanced feed.

And aircraft antennas tend to be vertical, at least the ones on the
ground, so orient it that way.

My phone number is 021-561-4959 and is unlikely to change. But what you may find as a result of a wecome call is anybody's guess.

I can well understand your interest in J.C.Maxwell's history. The Scots family was not very large. It is fairly likely you have connections. Should you enquire further then, as perhaps you have already found, a google on "Maxwell" is a good starting point. At the age of 13 he had already established mimself as a budding genius. His professional career is well documented.

But I can't resist the opportunity to add, it was Heaviside's self-taught nathematics which taught the world how to understand radio waves in all the world's text books.

I think serious family research work would have to begin at home in the States. A visit to Edinburgh would be more profitable than a vist to London during a holiday visit.

Another visit to a high-class tailor whilst in Edinburgh on holiday would eventually fit you up with a genuine Maxwell tartaned kilt. I expect you know that a kilt is a heavy, pleated, woven skirt, with a sporan to contain your loose cash, under which is nothing in the way of clothing. Many Scotsmen still wear them and not on ceremonial occsions. Furthermore, Scotswomen are proud to be so accompanied.

Yours, Reg, G4FGQ

Of course, aircraft need to communicate in all directions around, so vertical polarization makes sense.

In level flight, VHF aircraft antennas tend to be vertical. See the submarine Pampanito (at dock in San Francisco as a museum) web page for SCR 522 specifications. This was an AM VHF radio used in many warplanes in WW-2. It was supplied with a "1/4-wave vertical antenna". AM and the VHF frequencies above today`s FM broadcast band, and below the 2-meter amateur band, are still used for aircraft radio traffic.

Best regards, Richard Harrison, KB5WZI

Ger,
You should be able to add an external antenna to your new radio
but don't expect 'perfect' reception of other than local stations. I'm
afraid reception would never be as good as on the 'cable', but that
doesn't mean it won't/can't be pretty good. A 'closed circuit' system
like the cable will always be 'better' than broadcast reception.

Sorry about delay, had hard drive crash, slowly recovering.

We should change the subject, or W8JI will take credit for it :-)

Mechanical packaging done, also simpler version of Baby DRone is done, I am putting picture of it on the web. Farming out the cases and PS manufacturing. Working on fine tuning the architecture and gathering requirements for features. Had SM5BSZ of Linrad fame here and did some work on circuit design. Coming along nicely. Just had hard drive crash (IBM) after telling everybody to back up, while being lazy to do it myself. :-(
Enjoying working with nuts and volts, they don't argue with me, just some times don't work as they supposed to, but that usually can be fixed while some people have much higher resistance (or loss :-)
Stay tuned, coming soon to your shack.

73 Yuri

3142. Dumb question?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-12 15:41:20 UTC

Source record: 89663

I was having a discussion with another ham about dipoles and dipole lengths, and a rather silly question came up that neither one of us was sure of the answer. If a dipole is using INSULATED wire, can the electrical length be altered by just wrapping the ends more or less around the antenna wire when attaching the end insulator? Or does the INSULATED wire need to be cut? He thinks it does shorten the dipole, I say it doesn't. Hope he is right, it makes 'pruning' dipoles a lot easier.

Thanks

Hi Ger,

Go to radioshack and get a 300 Ohm to 75 Ohm TV adapter. The 300 Ohm
side is with the free leads. Cut off the leads and with extra wire
connect the ends together in a large loop (about 1 meter around). Put
receiver inside middle of loop.

How so? It's on topic. If this is the one I'm thinking of, it is a recording of a BBC radio spot on the role of amateur radio operations during the World Trade Center emergency.

I have lost all previous contributions to this thread.

But Jimmie gave the description of his radial system -
> >
> >12 12f t wires, Center ground stake 10 ft long, far end of each wire has
a
> >stake about 3 ft long. These are used more to just hold the wires in
place.
>
plus a brief description of type of soil and moisture content. I guessed at
wire diameters.

From which I deduce the following input impedances -

AT 1.9 MHz AT 7.0 MHz
---------- ----------
10 + j0 13 + j11 ohms.

Uncertainty = +/- 3 ohms which is adequate for the intended purpose.

The above figures have been obtained using programs ENDFEED and RADIALS2
(two different modelling methods) and averaging the results at soil
resistivities of 100 and 300 ohm metres. Programs can be downloaded in a
few seconds from website below. Calculating time no longer than needed to
enter the simple data.

In practice, only the resistances matter because the reactances are tuned
out simultaneously with the antenna, equivalent to minor readjustments of
the tuner. The resistance values, in conjunction with calculated radiation
resistance can be used to calculate radiating efficiency.

If Jimmie should ever measure input resistance with similar uncertainty (not
too difficult) then I should be pleased to hear his results.

I have never seen a 2010 so don't know what kind of inputs it has. If it has balanced inputs, connect the feedline directly to it. If, as I suspect, it has an unbalanced coax connector, use the 75 ohm balun.

Simplest way is to just thread the wire thru the insulator and and twist the ends together. Since a dipole never (well, rarely) comes out exactly right anyway, you're gonna end up pruning/lengthening it anyhow. If you do twist the wire back thru the insulator, yes, it will affect the length. If you are talking about cutting the internal (radiating element) wire SHORTER than the insulation, that doesn't make sense; the insulation is not strong enough to hold the thing. So, just thread the wire thru the insulator and twist the ends back onto itself. Then prune/lengthen as needed to resonate.

Thanks Doc, but don't you miss my point?
I *don't* want to use an external antenna - I want to use the co-ax cable
input.
There are channels on the cable which I can never receive with an external
aerial.

You may not get very good results.
Some VHF TV antennas are built NOT to receive the FM broadcast band, so as to avoid front end overload. A smart TV antenna designer would also reduce gain in the aero bands, and the commercial FM bands for the same reason.

It may work well enough anyway.

Ger,
If you don't mind some disassembly & soldering there is a good way to
deal with this. I did this 'mod' to a friends portable stereo so he
could use a coax-fed external antenna at his cabin. You'll need a
bulkhead F connector (available at Ratshack) and a small stretch
RG-174 coax (you could just use 'plain wire' if you don't have some of
the coax laying around), a drill and a soldering iron. Open the radio
and find where the whip connects to the circuit board - typically
there is a short stretch of hookup wire from the whip to the board.
Then unsolder the hookup wire from the board. Next, find an open area
on the radio cabinet and drill a hole & mount the bulkhead F
connector. Strip each end of the coax and solder the center conductor
where you unsoldered the whip, then solder the shield/braid to a
ground trace on the board. At the other end of the coax solder the
center conductor to the center pin and the shield/braid to the 'shell'
side of the connector. Reassemble and your'e done. If you want to
get fancy, you can also install a switch so you can choose between the
whip and an external antenna.

Hope this is helpful,
Howard

I had really not given it a whole lot of thought unti gettin invovled in
this thread but I am beginning to think that my sort of unique soil
conditions may effect my ground system considerably. With the moist, top
soil and clay at the lower levels I am getting a good primary power ground,

but now I dont think my RF connection to earth is very good at all ass the counter poise is in some fairly dry sandy clay. Wife says that when I installed this thing back in '94 that she remembered me putting in some longer wires than the 12 12 ft wires. At this point I am thinking maybe is was 8 12 ft wires and 4 1/4 wl 20m wires. I know the origonal plan waas to put in the 12 ft wires and 1/4 wl wires for several bands out to 80m with 3 or 4 wires for each band. I know I didnt do it for 80M but now I must admit I am not sure about other bands. I may have put in other radials for 20 and 40 meters. Shortly after this I almost totally gave up radio until recently.

I just remove a foot or two of insulation from the end of the wire,
before threading it through the insulator, and wrapping it back upon
itself -- that's possibly stronger mechanically, and avoids your
question completely :-)

Tom and others,

I'm very interested in what you work out. I just moved into the city and have an old house with a big attic. There is really no place on the lot (very small 2500 sg ft lot) to put any antennas. The attic is the third floor the peak being 30-35 feet above ground. There is no metal in the attic accept one condiut for a light and the cast iron soil pipes for venting the drains.

I have an AH-2 tuner that I am hoping I can make work with my kenwood TS-690S. I do have a little ICOM 760 mobile that I will use if I absolutely have to but that's really for my car (not currently installed).

So any thoughts on strait or loop. For strait I can go 50' Also should I run COAX from the main floor to the tuner in the attic and use the castiron soil pipe as ground OR should I have my 50' straight and then bring the antenna on the outside of the building down to ground level (inverted L) and keep the AH-2 in or very near the shack?

Thanks,

Kevin N9JKP

Sounds like the fence would make an excellent ground plane! Check and see
if it's grounded. If not, load it up as an antenna. :)

Just ground the fence and use it as a ground plane for a decent antenna.

As there is not a rec.radio.news.articles.about.radio and radio is of interest to most people here (apparently, not to you. What do you use your antennas for, decoration?) it fits here a damn site better than on alt.candlemaking. Thanks for your response. I had a spot in my bozo bin that needed filling. You'll fit nicely.

Thanks for that.Unfortunately this does not allow AOPRO to work.
Seems like I will have to load DOS into the computor.
Fortunately I can still use the program on another computor until I sort it out

Consider the input impedance on 160m. With 1.5 kW the voltage at the base
of the antenna is likely to be in the 20 to 30 kV range (about 5 - 7.5 kV
with 100 W) . Also for an "L" network, suggest you use a series "L", shunt
"L" configuration. Series "L" shunt "C" requires very large values for the
shunt capacitor.

Its not clear what you have in mind, but -

Doubling an antenna wire closely back on itself over a short length has the effect of shortening overall length of the antenna just as if the the doubled-back portion has been cut off.

Where the wire is double it behaves as a single wire of slightly greater the diameter.

"Reg Edwards" <g4fgq.regp@ZZZbtinternet.com> wrote in message
>
> I think serious family research work would have to begin at home in the
> States.

I've found the hardest part is linking the old scottish family history
with the later U.S. history. It seems many fled Scotland for various
reasons during the years, 1600-1700's, and records are scarce. I have
pretty good records of the Scotland Keith's, and I have traced my U.S.
history back to appx 1790-1810 VA., but can't find links to trace back
to Scotland. So it's like a missing gap. But there are pay sources
with possibly more info that I haven't checked yet. "IE: ship records,
etc".
There were Keiths in New England "MA." as early as the 1600's, but I
seem to be linked more to a VA. point of entry from the records I've
seen so far. The old Keith history in Scotland is quite well known as
they were quite a cast of characters, but it's like it hits a brick
wall at the point the various family branches came to the U.S. Hard to
link the two in many cases, unless you really scour all sources. Also
early U.S. history and documents can be meager to nil. Myself, I hit
the brick wall at the end of the 1700's. 1800 onward, I'm pretty
solid. I've traced back to my g-g-g-g-grandfather just using the web.
Back into the 1700's is meager. So even though I'm most likely related
to some of the old big wheels in Scotland, I have no idea which line I
would come from. There are so many lines....The 1700's must have been
a rough time in Scotland for a family with the land and general wealth
the old Keith clan had, to decide to split up and split town for the
new world.

A visit to Edinburgh would be more profitable than a vist to London
> during a holiday visit.

Most of the Keith clan was centered around Aberdeen. They founded one
of the old colleges there, and Dunottar castle is the old Keith family
castle. Mel Gibson filmed certain parts of "Hamlet" at that castle. Or
whats left of it anyway...It's in ruins now...
>
> Another visit to a high-class tailor whilst in Edinburgh on holiday would

> Scotsmen still wear them and not on ceremonial occsions. Furthermore,
> Scotswomen are proud to be so accompanied.

I'm not much for skirts myself. Rednecks in Texas generally don't wear them..:/
But there is a Keith clan, family tarton, coat of arms, etc, etc...Our tarton is kind of a green/blue plaid mix...

One story of the early Scotland Keiths can be found at:
http://www.thekeithclan.com/

Kind of interesting...We have a pretty colorful history, but not all is that good...
There was a long running feud with another clan due to some acts involving some of the Keiths..Resulted in the death of a girl one of the Keiths fancied..."kinda long story, but it can be found on the net. "That started a feud which lasted for many, many years. I think it just recently finally ended with both clans finally getting together and forming a truce.. MK

Jim,
It does shorten the antenna. Not exactly as much as if the 'extra'
wire were cut off, but close enough for 'gumment' work. The
difference won't make enough difference at HF to make a difference.
'Doc

3177. non-inductive resistors: metal-film vs carbon ?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-13 10:04:00 UTC
From: n1jpr@hotmail.com
Message-ID: <95a201e0.0409130204.7bafd05f@posting.google.com>
Source record: 89598

I shredded a few carbon resistors and noticed that many have the carbon layer laid out in a spiral pattern around the cylindrical core, up to several turns.

I also shredded a few metal-film ones, but could not figure is the metal was on a single layer or not, and how it was connected to the leads.

I wonder which best approximates a non-inductive resistance.

Do "spiral" carbon resistors have a significant inductance?

Do all metal-film resistors have a single layer, or are there some multilayered or (G_d forbid!!) spiral-layered, with plentiful capacitive bypass???

I have found a set of 16 x 100 ohm / 2W metal-film resistors which I am ready to assemble them into a 400 ohm / 15W (derated) terminator for a T2FD, but I'll wait for advice...

new 2m repeater on space station
a new 2m repeater is now operating on the
international space station 24 x 7
the uplink is on uhf 437.800 and the downlink is on vhf 145.800
no tone burst or ctcss is required
the radio is a kenwood tmd700 operating in remote crossband mode
it just retransmits on vhf what it hears on uhf
so if you are getting through you can hear yourself
on the downlink

anyone can work it using a co-linear

to see where the space station is 'live' check

http://science.nasa.gov/temp/StationLoc.html

for 3 days in advance predictions download the pcsat decoder program

http://www.ui-view.com/uiview32/pcdec242.msi

when the iss repeater is being worked the audio may be streamed in the
amsat
conference server on echolink so anyone anywhere in the world can
listen in

Also the series inductor should have a very high Q for 160 m. A Q of 1000
will loose about 30% of your power.

It is kind of hard to describe, but I guess 'doubling it over' would be closest. I've always cut extra length off, but the downside is cutting too much off. I ask this question because of a discussion we had about dipoles: I have an Alpha Delta DXEE that is near worthless on 40, but I would sure like an easy way to attempt to get it resonant on 30, without cutting the end 40 meter wires. My friend suggested just 'doubling the wires over on the ends to see if I could shorten it enough to get it in close. My club has an antenna analyzer, so I may give it a try.

Thanks

Reg, I have several documents about JC, and at one point on the internet I learned that his genealogy is available for viewing in the JCM museum, which I believe is in Edinburg, but not sure. My clan came from Glasgow, so there may be no connection.

>But I can't resist the opportunity to add, it was Heaviside's self-taught

I'm well aware of Heaviside's contribution to organizing much of Maxwell's work, which wasn't suffuciently organized for general use. I have original copies of a 3-volume set of Heaviside's books, plus an original copy of Hertz' "Electric Waves."

Very interesting, Mark.

My Maxwell ancestors kept a solid record beginning with g-g-g-g grandfather born in the late 1700's. My aunts, my dad 's sisters, organized the data on a long sheet of grocery-store wrapping paper, which I put into the computer using the LDS program. So I have the data prior to their leaving Scotland. What I need now is data preceding that grandfather, which can only be found in Scotland.

However, I'm not as much interested in going back farther, I'd simply like to know if any of my lines crossed any of JC Maxwell's, which is why I'd like to see his genealogy list in his museum.

Good Luck with your search, Mark,

Hi Matt,

Folded Dipole, bent into a circle or square with care not to bring the
opposite ends into contact. The feed point half should have a thinner
thickness than the folded back half.

Message-ID: <3200347.0409130940.43919ace@posting.google.com>
Source record: 89612

Metal-film and metal-oxide resistors are commonly done as a spiral
like the carbon film ones you describe. It's possible to find RF
metal film resistors which are relatively non-inductive, but clearly
the spiral ones will have an inductance about the same as a coil with
the same dimensions and number of turns. OTOH, that may not be a
problem--see example below. I've put a couple 100-ohm 2-W metal-oxide
resistors in parallel, with very short leads, and tested the
combination for return loss and found it to be better than 20dB r.l.
(1.22:1 SWR) out to beyond 150MHz. As they say, your results may
vary. But in any event, if you can use the resistors you have to make
a 50-ohm load and have a 50 ohm SWR meter you trust, you can get at
least an idea of their performance at RF.

Cheers,
Tom

(Example: say you have a 100 ohm metal-oxide resistor which is a
four-turn spiral 0.25 inches in diameter and 0.5 inches long. Its
inductance will be about
40 nanohenries, which less than j8 ohms at 30MHz. As a non-precision
load, that probably won't be an issue at all.)

I would not go as far as to say that.
With my desktop which is old I loaded it with two browsers
Windows 2000 and Windows 98 to get the DOS ability.
With the lap top just adding a Dos segment without loading the memory
seems to be the way to go. Understand the local University uses a
special program for combination of DOS with XP so it is not
insurmountable.

Not to diminish Heaviside's contribution, it was Gibb's work that led to the
present mathematical expression of Maxwell's equations.
The Heaviside equation survives to this day as the description of the
electromagnetic field of a moving charged particle.
But since Gibbs was American I'm sure you Brits will argue.

Or use one of the low-inductance metal-film/metal-foil types. Both
Vishay and Caddock offer resistors which have low levels of parasitic
inductance and capacitance.

Ferexample, Vishay quotes their VPR220Z precision-foil power resistors
(TO-220) as having no more than 0.1 uH of inductance ("due mainly to
the leads") and no more than 1 pF of capacitance, with typical values
being half to a third of those.

Caddock has similar parts, and several of the Caddock lines are
easily available through Mouser.

I have run a number of NEC models (NEC-Win Pro), for ground mounted verticals with a radial system, using the Sommerfeld/Norton ground models (usually in the range of: Sigma = 0.02 S/m Er = 17) -- although not for the specific dimensions indicated. My models would be approximately 0.001 wavelengths above ground (as per Cebik: Basic Antenna Modeling). The input impedance calculated is of the order of 1.5 - j1500. From these data it is relatively trivial to estimate the required Q of a series inductor.

I have been very interested in such antennas, but have never actually gotten around to building -- just modeling! If the original poster is interested, I would be very happy to model the specific dimensions.

Based on Terman's "Radio Engineers Handbook" dated 1943, pp 31 - 53. I have written a program In MathCAD Pro, which indicates a coil made from 1/4" copper pipe, 12" long, and 3 inches diameter has an inductance of 39 uH and a Q of 1132 at 1.8 MHz. (6" in diameter and 24" long shows a nominal Q of 1600). To be honest I have never built such a coil, and it would probably be very difficult to measure. I agree that typical "Airdux" coils have a Q in the range of 300 or so.(Silver plating, or gold, would also be desirable to prevent lossy copper oxide build up). Anyway if you are interested I can send you the MathCAD file. I would be very happy if somebody could check my math. It think the point I was trying to make it that electrically short antennas have such a low real input impedance that building an efficient matching network is challenging to say the least. Even if such networks are feasible the huge voltages developed at the base could prove to be a problem.

In fact, there are few countries, and Britain is definitely not one of them, that teach or speak proper English. It is a language butchered in pronounciation by all that England influenced, and was only corrected in teaching and pronounciation in America. We speak English, not an adaptation of it. If your understanding of this fact is lacking, there are many places for you to correct your deficiency, but it will not be here.

I beg to differ!

I don't think the word "Hi" is English yet it's the ubiquitous
greeting in the US (and unfortunately over here in the UK also).
Why do Americans write "meter" for "metre", " thru" for "through",
"dove" for "dived" , "I've gotten" for " I've got", etc, etc?
Somehow I don't think the Pilgrim Fathers brought all that over from
the Old Country!

Americans speak American and we speak English ... 'nuff said!

The input resistance of 1.5 ohms you quote implies an extremely good ground system. I suspect that very few people, particularly ones putting up such a short vertical for 160, have the room for that elaborate a system. As ground loss increases, the fractional loss caused by the inductor decreases. So I don't agree with your blanket statement that an inductor with a Q of 1000 will lose that fraction of the power. It might, if a person had an extremely elaborate ground system, but not otherwise.

Incidentally, although 30% power loss sounds impressive, it'll reduce the signal less than 1.6 dB.

So it won't be worthwhile for most people to make heroic efforts to produce extremely high Q loading inductors. (And, even if they can make one with a Q of 1000, it would have to somehow be suspended well above the ground and away from other conductive objects in order to retain that sort of Q.)

Hi,
I am contemplating a pep reading wattmeter so I can check the output of my HB amplifier. Consequently, I am putting it right on the output of the amp. The output of the amp should always see 50 ohms because it will be feeding either a 50 ohm dummy load, or an ATU tuned to 50 ohms. With that in mind, I am simply using a resistive voltage divider, to get a voltage sample, and squaring it with an AD633 multiplier. This seems like a simple, cheap way to get watt info. assuming you will always be working into a near 50 ohm resistive load. Anyone see any reason why this will not give you a pretty good indication of your power output? I realize that the load may not always be exactly 50 ohms, and that there are losses in the ATU.
The reason I have not tried getting a current sample and using the conventional VI COS Theta with the multiplier is due to the additional complexity of circuitry. It is also difficult to get accurate current samples over a wide frequency range. By making everything resistive it somewhat takes the frequency dependency out of the problem. Thanks.

I recommend Bill Bryson's book "Made in America"- a very readable account of
how American English has developed, with bits of the development of English
English thrown in.

Even in England, English usuage isn't universal. At least, after nearly 28
years in "the south", I still speak proper English ;-)

Yes, agree with everything you say. I have measured my ground conductivity as 50 mS/m, so it is possible I used that figure to arrive at the results. Much of Alberta and Montana have very high ground conductivity in the order of 15 - 40 mS/m (Reference Data for Radio Engineers, 6th ed, pp 30-7, 30-8). I must admit to being fixated on super high Q inductors to minimize matching network losses. Your figure of 1.6 dB loss with a Q of 1000 -- based on a 1.5 Ohm resistance is of course correct. Just the same I plan to model the vertical, as described in the original post, and see what I get for various soil conditions, and the loss effects of some typical Qs. I know it has all been done before, but enjoy doing it just for fun.

That's all well and good, but he wants to work over a wide frequency range.
Any L network will be a compromise. The Q as well as many other parameters
will have to be considered.

Jim -

Let's get back to your query. The broadcast FM band (88MHz to 108 MHz) is
just above Broadcast TV Channel 6 ... so a TV yagi antenna designed for
low-band VHF TV (Channel 2 - 6) or specifically for Channel 6 will do quite
well.

The civil and commerical airband starts above the FM allocation (108 MHz to
136.975MHz) to the beginning of the commerical VHF allocation (136 - 168),
Channel 7 is at 174 MHz

Here is some pertient inforamtion from Bob Colegrove and an older German
posting about this Sony radio Sony 2001D (also known as the Sony ICF-2010).

Bob Colegrove's document Coupling MW and LW antennas to the Sony ICF-2010
http://www.sdxf.org/alfa/dxinfo/coupling_MW_and_LW_antennas_to_the_Sony_ICF_2010.pdf

Building an Antenna mathcing device
http://www.hard-core-dx.com/nordicdx/antenna/special/2010ant.html

About the antenna circuit and external antennas
The following information is from an older posting,
<38EB4AAD.7C7D5EC6@yahoo.com>:

1.. The ext. antenna socket is "hot", i.e. powered through a 470 ohm
resistence + 100 uH coil. This means that it will deliver approx. 10 mA DC
current to the external antenna circuit. The coil is to prevent "polluting"
the power circuit of the radio with radio frequency signal. Evidently, the
purpose of this arrangement is to "inform" the accessory antenna when the
radio is turned on. In case of the Sony AN-LP1 it turns on the antenna
without need to use the antenna power switch. However, the 7600G will NOT
power the antenna, the 10 mA are not enough to power the amplifier circuit.
The power for the AN-LP1 comes from its own batteries. You can use this
feature with any active antenna by including a proper power-up circuit - a
nice feature if your active antenna is located far away from the radio and
you want it to turn on and off automatically when you use your radio.

2.. You can connect any other antenna (provided it is correctly designed and installed) to the EXT ANT socket without risking to damage the radio. However, if the external antenna circuit has low DC resistence, it will drain some current from the radio. Therefore, you will experiment slightly higher power consumption from your batteries (up to 10% at normal listening volume). You can avoid this current drain by including a small ceramic capacitor (1000 pF) in series with the antenna circuit, however I don't think it is really necessary.
3.. The 7600G has some basic protection build into the EXT ANT input circuit. Any static buid-up will be drained off via the power circuit mentioned in point 1. It also includes a diode pair (1SS123) to protect the input RF amplifier FET from damage due to too strong signals or an accidental connection of the antenna to a low voltage AC source. IT IS NOT A SUBSTITUTE FOR A PROPER ANTENNA GROUNDING AND LIGHTNING PROTECTION IF YOU USE AN EXTERNAL ANTENNA - YOU STILL NEED TO PROPERLY GROUND YOUR EXTERNAL ANTENNA AND PROTECT YOUR RADIO, but it builds some margin of safety to protect the front-end FET - a common problem with the Sony 2001D (2010).

As I understand it, the typical low-band or full-band VHF
television antenna is almost always a log-periodic, rather than a
Yagi. Yagi antennas having a substantial amount of gain are rather
narrow-banded, and won't cover the whole low-band VHF subband
properly. Log-periodics have only a limited amount of gain, but can
have a much wider bandwidth.

I think the only VHF-TV-band Yagi antennas I've seen were
single-channel types.

A full-VHF-band (channels 2 - 13) log-periodic antenna should work
very well on the broadcast FM band, unless it has a built-in FM trap
that cannot be defeated.

Mark
In the 1600s the prime point of departure was the West India Docks in
London. East India docks were for Australia. Actual records of
passengers
have been put on the computor by the Mormans.During those times seamen
were very prone to accidents and on reaching the U.S. were not hired
for the return trip. Many of these such as those with broken limbs
stayed in the U.S. when they were healed and headed into the far lands
and became trappers and traders. There are stories of some that made
good along the Mississippi and even had towns named after them (
Gaylsburg I think was one of them) The point that I am making is that
not all were emigrating passengers because many missed the boat for
the return trip for one reason or another. As for the person who
thought his clan came from Glasgow that was a real surprise to me as
we normally just called them Catholic or Protestant "gangs" Most of
the Scots that were pushed out of the Highland Light Infantry finished
up in my part of the military and certainly gave credence to the
stories of Glasgow and the Goballs. One member from Glasgow asked if I
would write a letter for him to get reinstatement to a soccer leave.
He told me he was suspended "sine die" to which I asked why.Apparently
he knocked the referee cold after an augument on the fielde. I
declined to write the letter expressing his remorse.

Hi, Mario

Thank you for this response.

Of all the replies that I received, you came closest to the information I
was looking for.

Even those recommending "phased arrays" failed to point me toward practical
information.

I have the tech-savy to build the circuits shown in your link and to
understand the theory.

Thanks again.

The most accurate way of measuring power is to measure volts across a known resistance.

Good luck getting a straight answer here, and I won't try one, because
every technical answer related to power transfer is always wrong by
someone elses measure on this list.

That being said, I'd do it the way you propose, since it's simple and
repeatable, and probably close enough.

Dave -

I nice thing about growing up 60 to 90 miles from VHF & UHF TV stations (and not that far from Burlington, IA where Winegard still makes the antennas - and AntennaCraft is next door - where Radio Shack OEMs their antennas) is that you learn about fringe and deep fringe TV antennas -- and the Radio/TV stores tried ALL of the types mfg. by Winegard, Jerrold, ChannelMaster, etc.

When Jim mentioned a dipole, reflector and 12 directors ... I have seen this on a long boom yagi (just like the 2 meter 11 to 18 element antennas) and as a log-periodic.

A photo is worth a thousand words.

Could be, but short dipoles can also be difficult to match, although as long as you do not go below a quarter wave it should be reasonably ok. Even with 450 Ohm ladder line the losses can sometimes be very high, not to mention the tuner losses, and, like the vertical, very high voltages.

The thing I like about verticals is the excellent low angle radiation. I have been playing around with NEC models of 32 ft verticals all evening, but not satisfied with the results yet. Roy Lewallen makes some good points, so you may not need to build a 2 ft long gold plated coil yet! Somebody else also pointed out that you want to use the vertical on other bands, which will make for a complicated tuner. I have been trying to make up my mind about 160 m antennas for about a year, still not sure what I want to do.

Tom W8JI talks about coils on his page and
if my memory is correct he has never measured a Q beyond 300
I use the 200/300 figure for my modelling and use as much as 800/1000
for capacitors. I am not competant enough to do any checking
of your particular program but I suspect your answers are in error
and await guru comments with interest

Hi Frank,

Not to raise your hopes on hi Q, but step back and consider: Why would current want to push its way through copper oxide when there is so much conductive copper a micro-inch beneath it? This is like saying insulated wire is non conductive because the plastic layer has so much high resistance that current can't flow.

Copper oxide is only an issue if you are trying to penetrate it for a contact (like in a switch, or a poor connection - tighten the screw).

Hi Gary,

If you are thinking of Eï¿½/R, you should note this is division, not multiplication. As such you will need an inverter ahead of the first product and then a second multiplier to complete the squaring. Then you would have a problem of dynamic range (not much).

I would suggest you look into turning the voltage into a log representation so you could then have a linear power scale. Adding logs is much simpler form of multiplication too and logs give much more dynamic range. You may lose out in resolution, but if you are driving a common 3ï¿½ digit converter for readout, you can recover that.

yes...the low angle of radiation is something I have been trying to achieve on 160, but still will allow me to use the vertical efficiently on 20 thru 80 and with a few contacts on 15 thru 10 meters.
It has to work at least as well at its current configuration on 20 meters...which is a 1/4 wave ground plane cut for 20 with 4 radials. Feedpoint is up at 18'. on a grounded aluminum mast.
I have done some more playing with Eznec also and think I can enlarge the capacity hat so that the efficiency is a bit better on 160.
I could always go back to what I used on 160 years ago at the bottom of the sunspot cycle....just feed one side of my 450 ohm twin lead to the ant tuner with as much wire I could bury for radials. The thing was resonant at the upper end of 160 and I did make a few decent contacts.

Why complicate matters?

All Gary needs is a diode, a capacitor, a resistor and a micro-ammeter.

3229. Re: non-inductive resistors: metal-film vs carbon ?

Lots of useful replies - thanks to you all !

Dale W4OP:
>Your best bet for low inductance would probably be the carbon
composition
> ...they look like a perfect cylinder- no bumps on the ends.

Understood! I remember popping resistors that contained a blackish compound throughout the cylindrical body: I assume those were cabon comp.

Also, correct me if I err, they tended to be LARGER that similarly powered resistors that had their heat-generating portion right under the skin.

Dave Platt (dplatt@radagast.org)
>> Or use one of the low-inductance metal-film/metal-foil types.
and Tom Bruhns (k7itm@aol.com)
>> Metal-film and metal-oxide resistors are commonly done
>> as a spiral like the carbon film ones you describe.

I am satisfied that metal film/foil types do not come in rolled-up-foil geometry like some capacitors. This is good - no capacitive bypass. Also, avoids the same temperature gradient / heat dispersal issues of carbon comp.

OTOH, still no guarantee that a metal film resistor is non-inductive.

Cecil Moore (w5dxp@hotmail.com)
>> I have some non-inductive wirewound resistors. They
>> simply reverse the direction of the winding every
>> so often to obtain canceling fields.

I knew they existed, and saw them in catalogs, but never used them.

I have been tempted to use a high power, low resistamce inductive WW resistor as a coil in a regen receiver, just to see how well one can compensate for losses.... I bet both regeneration and tuning will be VERY smooth :(

Tom Bruhns (k7itm@aol.com)
> I've put a couple 100-ohm 2-W metal-oxide resistors
> in parallel, with very short leads, and tested the
> combination for return loss and found it to be better
> than 20dB r.l. (1.22:1 SWR) out to beyond 150MHz.

That pretty much cuts it!

I can easily test my 16 x 100 ohm resistors as a couple of 50 ohm dummy loads on HF. After all, a decent HF match is all I really need, and chances that a low "random" SWR will result if great reactance is added atop resistance is quite modest. Thank you for pointing out the obvious to my obviously obnubilated mind!

3230. 4nec2 simulation of a pvc sheet?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-14 11:11:37 UTC
From: Alex <no@spam.com>
Message-ID: <hhjdk0ttquhc141n48jsf714vas93rdsnf@4ax.com>
Source record: 89551

I have successfully constructed various 2400 Mhz antennas using the 4nec2 antenna modelling software (really great application, warm tnx to the author should he read this!)

What I would like now is to get a rough idea as to how close I can put the antenna elements to a PVC casing without disturbing the radiation pattern, SWR etc.

E.g. by putting a 2 mm lossless PVC sheet (with dielectricity constant = 7) 1 cm in front of the antenna element.

Is it possible to simulate this?

Alex

Hi Reg, Thanks for the reply. That will certainly work, but I would need a Log scale (or is it square) on the micro-ammeter. I want to be read 0-1500watts pep. Down around the 100 watt level things would get crowded. I bought some 3-1/2 digit multimeters from a company here in the US for $3 each. Bought 11 of them. Or I have a 0-1 ma movement that I have re-labeled the meter face to read watts, but it is a linear scale.

Not with a freebie NEC based program.

Also, Why are you using PVC? This stuff is horrible as a base substrate at 2.4 GHz.

73,
Chip N1IR

>If you are thinking of Eï¿½/R, you should note this is division, not
>multiplication.

Thanks Richard. What I am thinking is: assuming a perfect 50 ohm load, scale the voltage divider rectifier combo to give 10.0 VDC at full scale watts, 1500 in my case. I now have a relative power indicator as suggested by Reg. I can take care of the squaring and division by putting a Log scale(watts) on a 0-10V analog meter movement. But, what I intend to do is run the voltage divider signal to a multiplier whose output will be V**2/10. If V is 10. volts for 1500 watts then the multipier output will be 10.0 volts. let 10.0 volts equal 1500 watts on the meter scale. Checking another point, assume 500 watts, then the output of the divider will be 5.76 volts, and the output of the multiplier will be 3.33 volts, which is 33% of 10 volts. The wattmeter will read 33% of 1500 or 500 watts. The scale will be linear.
I have not seen it done this way before, although I am sure it has. For this method to accurate your load must be near 50 ohms. The AD633 is a cheap, easy-to-use multiplier chip. Using a +/- 15 VDC supply, it looks like it will have the dynamic range I need.

3234. Re: 160 thru 20 meter homebrew vertical system

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-14 13:18:31 UTC
From: Frank <ve6cb@telus.net>
Message-ID: <HcC1d.3888$yW6.961@clgrps12>
Source record: 89555

Could not sleep, thinking about all this stuff. Anyway have some data, which I hope agrees with your findings:
32 ft monopole, 32 radials of 25 ft each, 4 spoke capacity hat 6 ft horizontal. At 1.8 MHz.(Model elevated 6" to meet > 0.001 wavelength requirement of NEC). Also highly segmented at 2 segments/ft to get near base for feedpoint.

Perfect Gnd Zin = 2.9 - j880 gain/TO angle = 4.2 dBi <0
Avg. gnd (0.005/13) Zin = 6.7 - j880 gain/TO angle = -2.6 dBi < 25, and -6 dBi < 7
Good gnd (0.01/14) Zin = 4.9 - j880 gain/TO angle = -0.3 dBi < 22, and - 3.5 dBi < 5
V. good gnd (0.03/20) Zin = 4.1 - j880 gain/TO angle = +1dBi < 19, and -2 dBi < 4

Tuner analysis matching 4.9 - j880 Ohms , 1.5 kW input: Series "L", shunt "L". Series "L" = 76.2uH, shunt "L" = 1.9 uH most loss occurs in the series inductor.

Q= 300, 2dB loss, 938 W into antenna (and gnd loss), 550 W loss in series "L", 12.2 kV at antenna base
Q= 1000, 0.72 dB loss, 1.27 kW into antenna (and gnd loss), 224 loss in series "L", 14.2 kV at antenna base

The idea of building a "T" antenna is also very good, being much easier to match, and having very good low angle radiation. Makes me think I should try it!

I guess it shows that attempting to attain a Q of 1000 for a gain of 1.3 dB is pretty pointless. Without actually building such a coil and measuring it I cannot say whether it is possible. I have certainly seen claims of coil construction exhibiting Qs in excess of 1000. Silver plating of coils to prevent copper oxide is pretty much an industry standard. The analysis and proof of why is complicated, but something that sounds interesting. Will get around to it one of these days.

Another ham in Calgary (VE6WZ, Don't know him) has done some work on high Q coils (http://www.qsl.net/ve6wz/coil.), and provides a link (now dead) to W8JI. My calculations seem to show reasonable agreement with the program he used from K6STI, which does not seem to be available. I would certainly like to see some independent verification of the results. I am tempted to build a coil and measure its Q.

Who told you PVC was lossless? Stick a sample of it in a (2.4 GHz) microwave oven and see what happens. You could simulate it with a sheet of carbon impregnated foam, but I guess 4nec2 doesn't handle that either. If you need a radome, use foam polystyrene, commonly known as Styrofoam®.

>Also, Why are you using PVC? This stuff is horrible as a base substrate at 2.4
>GHz.

Because I can get a cheap PVC case which is otherwise suitabel for
weatherproofing the antenna. And because I have seen reported (I have
not tried it myself) that such material does not get heated in a
microwave oven.

The antenna elements themselves are sandwiched between (1 cm)
styrofoam sheets which should be lossless and have a dielectric
constant = 1 (almost). So the antenna elements would not be in direct
contact with the PVC case.

Have you got any other suggestions for a weatherproof case material?

>in my case.

Hi Gary,

1500W into 50 Ohms yields 274V which you then divide by 27.4 to obtain
10V.

>But, what I intend to do is run the voltage divider
>signal to a multiplier whose output will be V**2/10. If V is 10. volts for
>1500 watts then the multipier output will be 10.0 volts. let 10.0 volts equal
>1500 watts on the meter scale.

As you already have 10V by divider action, what do you need to
multiply? The chip offers two inputs one of which I presume is a
constant 10V? Something is missing here because you are still
dividing and if this through a divider at the output of the
multiplier, then you have jacked the multiplier's output to the rail
BEFORE the division (loss of dynamic range).

>Checking another point, assume 500 watts, then
>the output of the divider will be 5.76 volts,

500W into 50 Ohms yields 158V which you then divide by 27.4 to obtain
5.77V. OK

>and the output of the multiplier
>will be 3.33 volts, which is 33% of 10 volts.

More missing discussion. Like how does 10 ï¿½ 5.77 / 10 = 3.33? The
10's drop out just like before (a useless operation).

>The wattmeter will read 33% of
>1500 or 500 watts. The scale will be linear.

I find it difficult to observe how a non-linear (power) response
becomes linearized without an inverse (log) operation.

> I have not seen it done this way before, although I am sure it has.

Not by your description.

>For this
>method to accurate your load must be near 50 ohms.

That value is immaterial to anything but ONE value of power
representation. The nonlinearity of the response would force you to
have a table of Logs nearby to translate any other reading.

>The AD633 is a cheap,
>easy-to-use multiplier chip. Using a +/- 15 VDC supply, it looks like it will
>have the dynamic range I need.

No, it won't as I've already shown. There is a MUCH better solution
and far cheaper (FREE):

many tnx for your answer

actually I am using styrofoam already for the indoor model. But
styrofoam is too soft and vulnerable to make weatherproof so I shall
have to put it in a case made of something more rugged.

Evidently 4nec2 does not handle the needed simulation so I shall look
around for other software or maybe make a SWR meter and some practical
experiments...

PVC is not lossless, however...

I used PVC drainage pipe (white, 3 mm thick maybe) to make radome for 900MHz antenna. Specifically, directional patch arrays. It tuned them down a little bit (2 mm maybe over half-wave length.) I did not measure significant decrease of gain. The cover did not touch the radiator. When it touches, loading get significantly worse.

>1500W into 50 Ohms yields 274V which you then divide by 27.4 to obtain
>10V.
As you already have 10V by divider action, what do you need to
>multiply?

Hi Richard, I want 10.00 VDC to indicate 1500 watts on my 0-10v meter with a linear scale. If I run the 10 volts thru the multiplier (squaring) circuit I get (10)**2/10=10 volts. So far so good, and you don't need a multiplier.
>500W into 50 Ohms yields 158V which you then divide by 27.4 to obtain
>5.77V. OK

If I run 5.77v to my 10 volt full scale meter it will read 5.77/10*1500=865.5 watts which is not 500 watts. However, if I run 5.77 thru my squaring circuit I get (5.77)**2/10=3.33 volts. Now my meter reads 3.33/10*1500=500 watts which is correct.
If you plot the voltage across a 50 ohm resistor vs power V**2/50=power, you get a squared relationship. You can use volts to represent watts only if you scale the meter face correctly. I have seen wattmeters that did this. I believe the Drake model did. 0-100 watts took up the first half of the meter, and 100-1000 watts took up the other half.
If you linearize the voltage by squaring and scaling you get a nice readout with 100 watts being on the left hand side of the meter, and 1500 on the right hand side, and linear in between.
The AD633 probably uses log amps in realization of multiplication, I haven't looked at the internals. I have done multiplication with Log amps. I have to disagree on the AD538 being a better solution. One could use the 538, but the 633 is much simplier to use. Also I already had some AD633s

Sounds like you have found the plans for Oliver Swan's (original Patentee)
antenna. these were mostly made for six meters. K.L.M. , if I remember ,
aquired the patent, then proceeded to produce antennas for vhf, useing
this design. The original reason that he made these for six meters (Swan),
was 2 fold-- one, to improve the bandwidth of the antennas, and two, (remember
this was before cable tv was widely used) to limit TVI(an antenna with a built
in TVI filter !. A consideration for KLM useing this design was additional
bandwidth, consistant foo max gain (high gain antennas are pretty touchy about
gain over bandwidth). Hope this info helps, Jim NN7K

Oh, forgot to explain just HOW the Swan antenna limited TVI !
reason was that the antenna was relatively flat in gain, over 1-2
MHz of six meters. Above around 53 MHz, or below 49MHz, theoretically,
the antenna pattern collapsed, and the swr rose dramatically.
This was what was claimed, If remember the spin from those times! Jim

It all works for me in Excel. Squaring the voltage eliminates the need for any log stuff.

E = Root (P*R)

Scaled V is V / 273 but you'll have to go further to stay in the dynamic range of the multiplier. V^2 should be around 10V or whatever the mult can output.

W V scaled V V^2 V^2/10 Output ratio
1500 273.9 10 100 10 1
500 158.1 5.77 33.33 3.33 0.33
100 70.71 2.58 6.67 0.67 0.07

==========

I'll allow a wine-assisted imagination to wander around my own history.

I came across Gibbs around 1948 by accident while searching for more information on transmission lines in general. Google had not been invented. He appears to have made his name known (no doubt also in other matters) because of his "Gibb's Phenomenon", an overshoot of some kind in an extension of Fourier's Waveform Analysis. At the time I had no interest in 'overshoots' and forgot all about it. My ignorance about Gibb's other work has continued ever since. I appologise for no mention of his name in connection with tidying up Maxwell's work. And there's no reason at all to resurect the Boston Tea Party.

Heaviside died in solitude in 1925. I was born during a freezing 6-feet deep snow-storm 9 months later. I sometimes like to think there is a spiritual connection.

Mother was a little hard-working woman who took in laundry and clothes-ironing from the slightly better-off classes. Father was a 30-shillings a week iron-bolt header but the national General Strike was imminent. In his spare time he taught himself to drill holes in ebonite panels using a red-hot poker the smell of which began my technical education. But he could solve quadratic equations in his head without the use of pencil and paper or any knowledge of algebraic symbols. I never understood how he did it. Although he lived to the age of 90 he could never explain it himself.

<snip>

Around 1951, as a sideline with other duties, while working in the Engineer-in-Chief's Office of the British Post Office, I first became involved with the location of faults on transmission lines. Then, for a period, I specialised in faults on the then new deep-sea coaxial cables with submerged valve-type repeaters (amplifiers). Transistors were not good or reliable enough.

I worked alone but with the facilities of a shared workshop and staff. My boss was an ex-cable ship Cable Testing Officer, a Ph.D, I think next to the

captain in rank, who always said the only doctor in his family was his brother, a doctor of medicine. His name was Bray and he had the knickname, when not in his company, of "The Vicar".

<snip>

I became involved with reflection coefficients, etc., in the frequency range 0.1Hz up to HF using rectangular-waves and sinewaves. The Dollis Hill, Research Depapartment laboratories (the PO Bell-Labs) made me a 0.1 to 100 Hz, balanced-and-screened output transformer, to be used in a power amplifier, a test signal generator. The amount of 10-thou, mu-metal used in it necessitated a special order being placed on the lamination manufacturer.

I had to make my own precision 0-to-11.111 microfarad, 5-dial, variable capacitor entirely out of specially made polyethylene-dielectric metal-cased capacitors. Absorption with all other dielectrics was far too high at 0.1Hz to make accurate impedance bridge measurements. Mica was awful!

Incidentally, apart from research work, the only occasion this capacitor was used for a practical purpose was to locate a fault on a land cable when I was in Sweden. The embarrassed Swedish engineers were not aware the fault existed. Needless to say I promised aboard the ship on my departure not to include the incident in my report. And I didn't. The Vicar, with his cruel sense of humour, was not altogether happy but for technical political purposes I had him by the balls. He was really a kind fellow and before retirement he ended up as Head of the PO Engineering Training College.

Some years later I had the idea of donating the transformer and capacitor to the Science Museum in London. But some other equally sentimental collector had already stolen them. I sometimes wonder (2004) where they are now.

<snip>

But this is a long way from the much neglected Heaviside.

During the course of my fault location research I ran into a mental blockage. Ultimately, I had to translate the appearance of the reflected waves, as appeared on a 10 second persistance cathode ray tube, a function of time, into miles from one end of the cable. That is all the ship's captain needs to know before he can leave port and set a course. He can then retire to his lonely cabin with a bottle of duty-free scotch if he should so wish.

Eventually I discovered Heaviside's Operational Calculus. Lo and behold, winding the handle on a German mechanical calculating machine, there appeared on a sheet of graph paper the same shaped curves as on the long-persistence CRT. The fault locating equipment was eventually installed at oceanic terminal stations. I had the oportunity to use it on the first breakdown to occur on the relatively short Middlesborough-Gothenburg cable which, as usual, was due to an unknown fishing trawler in the north sea.

All the learned arguments on this newsgroup about SWR, the various reflections and virtual this that and the other, occur because time is

ignored. It is admitted time does complicate matters. But Heaviside sorted transient matters out, versus time, many moons ago.

It's commonly known that a square wave consists of a sine wave of the square wave's fundamental frequency, plus all its odd harmonics. Specifically, all components are in phase, and their amplitudes are the inverse of the harmonic number. That is, if the amplitude of the fundamenatal sine wave is 1, the amplitude of the third harmonic is 1/3, the amplitude of the fifth harmonic is 1/5, and so forth.

So we should be able to create a square wave by adding all those sine waves -- right?

It turns out that if we add the first few sine wave components, we have a fairly square looking wave -- but it has an overshoot at the leading and trailing edges. As we add more and more harmonics, the result gets more square, and the overshoot gets narrower and narrower -- but it remains, and with the same amplitude. Although the width approaches zero as the number of sine waves you've added gets infinite, there's always an overshoot for any finite number of sine waves.

This is one manifestation of the Gibbs' Phenomenon, which also applies to other situtations. There's a really nifty demo at http://klebanov.homeip.net/~pavel/fb//java/la_applets/Gibbs/.

3260. [OT] Rcvr antenna input impedance

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-15 09:08:21 UTC
From: Toni <post_to_usenet@hotmail.com>
Message-ID: <6h1gk09c88et0anvhpipo0jqdkragrqh2r@4ax.com>
Source record: 89481

Hi,

I have a Sony radio for SWL and I have seen that if I parallel a 300 ohm resistor to the antenna input the received signal drops considerably [1]. I think this means the receiver's input impedance is much greater than the normal 50/75 ohms. This makes me wonder two things:

- How can I measure the approximate value of the receivers input Z? I don't want to know the exact value, just to know if it is in the 500 / 1K / 10K range. I guess I can do this by paralleling increasingly valued resistors until there's not much effect on signal and assume that it about half that resistor's value.

- Having a 50 ohm feedline, would I benefit by using a 4:1 balun in reverse at the rcvr input? What kind of balun could I use for that? It would be great if it also provided some improvement of CMRR for noise picked by the feedline itself.

[1] I use a 100nF capacitor to isolate the 4~5 V DC level at the antenna input. I guess this DC may be there to feed some kind of active antenna.

tnx for your reply

But it seems to me that what you describe is not so much that the PVC
absorbs energy ("loss") but instead: that it unavoidably de-tunes the
antenna because of its high dielectric constant (about 5 to 9 I
understand). Especially when the PVC touches the radiators the
capacitance between radiator parts is markedly reduced because of this
phenomenon (anyway that is how I intuitively understand it...)

3262. dBW in S-unit and power strenght

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-15 10:56:16 UTC
From: Thierry <"to answer direct see http">
Message-ID: <41481fd2@news.vo.lu>
Source record: 89483

Hi,

A question about dBW and power at receive.
Among scales used in power measurement, there is the signal strength or noise level estimation, also known as the "dB below W" (dBW or SDBW). Its relation is dBW = 10 Log P, where P is the power expressed in watt :
That means that 100 W is 20 dBW into 50 ohms.

But usually, in propagation program (VOACAP, etc), the power strength at receive expressed in dBW is far below such values. I read somewhere the next equivalences :
- (minus) 93 ~ S9+10, -103 = S9, -127 = S5, -151 = S1.

With -93 dBW for a S9+10 signal at receive, that 'd mean that the power 'd be only P(W) = 10^ (dBW/10) = 0.7 watt ?
IMHO this power is much to low... What is wrong in this relations (or in my interpretation) ?

Thanks in advance

Thierry, ON4SKY
http://www.astrosurf.com/lombry

One S unit referencing 6 dB.
Some receivers has meter in dB over 1 micro V.

> With -93 dBW for a S9+10 signal at receive, that 'd mean that the power 'd
> be only P(W) = 10^ (dBW/10) = 0.7 watt ?

"W" mean level in Watt.

> IMHO this power is much to low... What is wrong in this relations (or in
> my interpretation) ?

P log * 10 = dbW

Reverse calculation:

dbW / 10 10^x = P

-93 / 10 10^x = 5,011e-10 = 0,0000000005011 Watt

PVC is L-O-S-S-Y at 2.4 GHz. The amount varies according to manufacturer. CPVC has the least loss of a lossy lot.

OK?:-)

Gary,
Comment I have is in your resistive divider. To keep the power dissipations in the resistors low, you will have to use large resistor values, but at RF these can be off 50 % or more. So, you will want to build what looks like a 'scope probe, with each of the resistors shunted with a capacitor, where the two RC products are the same. For starters, try something like 2 - 5 PF for the smaller capacitor. Do not use ceramic capacitors, except for NPO. I would build the thing with at least 2 scales, say 0 - 150 and 0 - 1500 W.

Hi Art, no problem. The fact is the work I have done is entirely theoretical. Not to mention that it is based on equations published in 1943. It does need some lab verification to satisfy my own curiosity. Another ham wrote to me, pointing out that inductors with a large length/diameter ratios will probably have errors in the inductance value predicted. Anyway more work needs to be done, but appreciate your comments -- and the comments of others on this NG.

==========

The trouble with Fourier when attempting to use him with waveshapes on transmission lines is that there is no fundamental frequency or cyclic repetitions. His infinite series are solely functions of frequency.

Whereas volts and current on lines are functions of time (the recprocal of frequency) and distance. That's where Heaviside's Operational Calculus comes in. In special cases (if you can find your particular problem in the long list of transforms and their inverses) his methods reduce to Laplace Transforms. But in general, as with Fourier, his answers appear as infinite series. Of course, infinite series pose no problems with present-day computers.

The very first problems were encountered by Kelvin with the speed and distortion and economics of telegraph-code signals on long cables. 0 and 1 signals change shape and merge into each other at high data rates. Fourier could not provide answers. Exactly the same problems still occur on high data-rate digital circuits and light-fibers, further aggravated by echos and reflections. But Heaviside's revolutionary mathematics, which so upset the old-wives of professors of his day and abolished the need for SWR's, did the trick.

Does not exist ! But well dBW = 10 Log P, this is not the same excepting
reading from right to left, Hi!
Your explanation is not one. refer my link for a correct explanations.
Anyway, how do you calculate the dBW on 20m with such a formula. Someone
calculated dBW on 10m, so we must be able to do the same at 20m...

But how ?

Hi Reggie,

In fact, computers do NOT use infinite series (at least not in commercial products) and only symbolic math packages are capable of emulating Fourier. The FFT, the Fast Fourier Transform developed by Blackman and Tukey ("The Measurement of Power Spectra," Bell Labs, 1958), implements the concept in finite series that are then "windowed" to create a period from any transient data. The consequence of this is that the spectrum blurs, or if you use different windowing functions to clear up the blur, the amplitude assumes a non-negligible portion of error.

"We face a three way compromise among effort, resolution, and stability (precision) of estimate.
....
"If, for example, a resolution of 0.1 cps is to be obtained from 6 pieces of record and is to furnish stability of ï¿½2 db for (on average) 9/10 of the individual estimates, then the necessary duration will be 150 seconds." (ppg 56-57)

No it doesn't. Free space can't extract any energy whatsoever from EM
waves travelling through it. Consider :-
The cosmic microwave background hasn't had it's power extracted by
the universe in all the time since the big bang. Conservation of
energy applies everywhere.

Just my opinion ;-) but it's allodoxOphobia.

Hi Toni,

This is something you could test yourself:
>- Having a 50 ohm feedline, would I benefit by using a 4:1 balun
>in reverse at the rcvr input?
with a before/after 300 ohm resistor application. Sure it isn't a 330
Ohm resistor? 300 is not a standard value. Also, is there any chance
this resistor is wire wound? Makes an important difference!

Alternatively, the same phenomenon should occur if you put the
resistor in series. Be careful to maintain ground in all tests.

Finally, what are you using as an input reference? The signal from
this same 50 Ohm feedline?

Buy a cheap passive antenna tuner, e.g. the YAESU FRT-7700
or the one from MFJ Enterprises.

Forget that idea with the resistors.

Hi Thierry,

S-9 is the reference point for a 50ï¿½V signal into the receiver's 50
Ohm input. This is -73dBM (level below one milliwatt). Translating
to levels below one Watt is performed by subtracting another 30 (the
milli) dB - hence -103dBW.

Power is a curious thing. Transmitter efficiency as measured by the
target population that receives the signal is pitiful. If every
person on the planet had a radio that picked up your 100W signal with
S-9 level, you would be pumping 99.9% of your 100W into the void
without anyone missing it anywhere. Efficiency < 0.1%

Given that you are NOT heard by everyone (they don't care to listen),
then transmitter efficiency plunges at least 7 or 8 more orders of
magnitude. Efficiency < 0.00000001%

True so far, but just you wait till the *BIG CRUNCH*. You don't
really think that our present Big Bang was the first one ever,
do you? :-)

> IMHO this power is much to low... What is wrong in this relations (or in my
> interpretation) ?
>

Your calculation of 0.7 W is wrong by many
orders of magnitude.

dBW = 10 Log(P)

-93 = 10 Log(P)
-9.3 = Log(P)
Alog(-9.3) = P
ALog (-9.3) = 5.012 * 10^-10 W
(5.011872336272722850015541868849 5e-10 by win2k calculator)
So the problem is much, much worse than you thought.

Try this scenario:-

You are in Belgium, I'm in the west of the U.K. about
400 km away. You transmit using 100W and I get an S9+10
signal. All seems reasonable? Say this is on 80 metres
so both our antennas are omnidirectional. My antenna
will only receive power proportional to the solid
(stereo) angle it subtends at your QTH. So the power
of 5e-10 W seems about right to me. Just think how
many other 80 metre dipoles would fit in around that
400 km circle. Then all the ones that would fit onto
a 400km radius hemisphere. They would all get a tiny
share of your 100 W!!!

Receivers are very, very sensitive or radio wouldn't
work at all.

A signal of 1 microvolt into 50 ohms is the same as
a power of 2 x 10^-14 W !!! (P = V^2/R)

Hope this helps.

vy 73

As others pointed out, your calculation is wrong and that .7 W is way too
large for received power. We receive powers in the -123 dBm (-153 dBW)
range easily and that's ok

However, it is not clear from your post just what you want to do/ask/learn.
What is your number too low for? What are you wanting?

My new location has a short narrow attic with a traditional shape --
gentle pitch from a raised ridge which crosses the house along the
long axis, like a triangular prism. I have a fan dipole from my last
location that I'd like to try to reuse. Will I be able to get away
with putting the longest legs of the dipole along the center line,
parallel to the ground, and then putting the shorter legs (what was
once an inverted vee) angling towards the corners of the roof?

center line

I know "everything works", but this is likely to be the only antenna I
can get up in time for the California QSO Party in a couple of weeks,
so I'm hoping that it'll be "good enough".

Thanks in advance for thoughts and suggestions.

Jack.

I found this on the net, which may help you.....

Alimentary Fourier Anal-ysis

(C) Copyright 1997 Gareth Alun Evans G4SDW

The Fourier Transform is rather like the Human Alimentary canal....

The Alimentary Canal takes food, and then transforms it into
something that is a function of the rear end, and hence may
be referred to as, "The Food-Rear Transform".

The Fourier Transform causes integration over a one second
period, and results in an infinite series of sines.
The Food-Rear Transform causes disintegration over a 12-hour
period, and results in an infinite series of signs...."Gents",
"Ladies", "Rest Room", etc. etc.

The Fourier Transform (Tukey's reasoning?) takes Time and
transforms it to a frequency spectrum.
The Food-Rear Transform takes Parsley, Sage and Thyme (Turkey's
seasoning?) and transforms it to a frequently active rectum.

"Laplace", literally, "The Place", is how you deal with
the transform.
"Walsh" is something you do to your hands afterwards.
"JPeg" is what you hang your jacket on to. It is a form of
compression such that you take up less space and spend less time
there (although the output may be more granular).

The Fast Fourier Transform must be done through an appropriate
window, otherwise an effect known as the "Picket Fence" problem,
also known as "Spectral Leakage", can occur.
Diarrhoea is known as the FAST Food-Rear Transform, and if done
through the wrong window can result in a problem (also known
as Rectal Leakage) all over the Picket Fence.

The Picket Fence problem is also known as, "Scalloping",
something which is normally done to pie crusts. In the old
days, pies used to be made with "Four And Twenty Blackbirds";
but nowadays, members of the Jay family are used. When you go to
someone's house for tea, you politely eat everything that is
put in front of you, but your reaction might be,
"Eat the Jay (Oh my God!) Tea???".
Similarly, the Fourier Transform is a great consumer
of e^(jwT)... "E to the j, omega, t".

The Fast Fourier Transform is famous for its Butterflies.
The Fast Food-Rear Transform is famous for its
Butterflies-in-the-stomach.

Dirichlet's are the Fourier Transform's conditions, without which
the result is divergent.
Diarrhoea Shits are the Food-Rear's conditions, with which the
result is VERY divergent.

Having experienced the Fast Fourier Transform, you are then faced
with the Inverse, which can be very daunting. It is a paper
exercise but it can be quite messy.
Having experienced the Fast Food-Rear Transform, you are then
faced with the "In Verde", literally "In The Grass", which can be
very daunting indeed. (The paper exercise can be quite messy.)

The input impedance will vary depending on the receive frequency.
It's something that isn't much worried about in radio design for
SW. As the radio's AVC circuits will make up for gain losses
due to mismatches. Also realize that the receiver's front end
noise is much less than the amount of noise produced by the
natural and man made environment. That would limit how much DX
you can do. A perfect match of antenna to front end would just
deliver more noise along with signal, and would be indistinguishable
from a mismatch with the AVC making up the missing gain. I'm
talking about around 10dB mismatches here.

My educated opinions on this matter are as follows--thisreport is very sugar coated: The Dutch decision broke up the original consortium and, in my opinion, severely degraded the success as originally outlined. The astronomical community is not happy: this is the first time that an international astronomy community has worked against itself.

This is NOT 'LOFAR' as defined, but a highly compromised derivative version. Holland is a very poor site location for these frequencies, because of the high population areas and extant HF/VHF use. Also, the cross polarization inverted V element is a poor antenna for the relevant passband.

A good link on the original plan is:

http://www.lofar.org

Thanks for checking my calcs. Steve. I had to do what your spreadsheet did by hand. I should note that since I have to convert the voltage to the multiplier to DC, at 1500 watts we are working with 273*SQRT 2 or 386 volts. I size the divider so that 386 this gives 10.0 volts to the multiplier. With a dual polarity 15VDC supply, the multiplier has enough dynamic range.

Well, I hadn't thought of that, so I'm glad I asked the question. I had planned on using a 200k 1/2 watt carbon and about 5k 1/2 watt for the divider, keep the leads short, and locate it a close as possible to what I think is 50 ohms in my system.
Do you think it would be worth the time and effort to do an rf frequency sweep of the divider to see how accurate it is? I realize this method is not going to be dead accurate, but I was hoping for better than 50%.

Hi Gary,

I like the topic of discussion. I've been working with the AD633's for several years now. I'm wondering why you vered away from the V*I idea. That would make your calculation good for any load. Instantaneous V times instantaneous I will give the answer whatever the relative phase happens to be. Maybe I'm missing something?

Hi Jim, this didn't show up on my ng reader for some reason, hope you don't mind me replying on the ng.
The reason I didn't the V*I route, which as you say, is the obvious way to go: I did not feel I could get accurate V and I samples over a wide range of RF frequencies, with my limited knowledge and resources. I thought a simple resistive voltage divider would make it real simple, and somewhat frequency independent. I am now finding through the responses I have gotten, that resistors will be frequency dependent as well. Darn.
I recently tried to use 633s in an application at 60hz to detect when a very large generator went from producing power (generator) to absorbing power (motor). I found that the potential and current transformers I was using introduced an unacceptable phase shift from primary to secondary. I tried several different types but finally took another approach. This is probably another reason that steered me away from the V*I solution.
If you have a simple way to get accurate V and I samples for say 3-30MHZ I am all ears, and forever in your debt.

Hi Gary,

I just measured some random 1/2W carbon resistors with an MFJ at 30 MHz.
This is not a precision instrument, but shows a trend.

Nominal Measured
5.6 K 0 - j586
220K 0 -j 600
1.8K 99 - j539 (convert this to parallel form)

As a sanity check

11 Ohms 12 + j4 (some lead inductance here)

What this is tending to show is that the resistors are showing a shunt
capacitance whose reactance is about 600 Ohms at 30 MHz. That is about 9 PF,
which seems high. I was expecting more like 1 PF. I want to redo this at a
higher frequency, might be out of range for the MFJ.

I notice my Kenwood power meter uses a capacitive divider for the voltage
sample. A friend of mine built a meter along the lines of what you want to
do. I will ask him what he did.

Tam

Source record: 89514

It's much more likely that the shunt capacitance is in the MFJ.

Calculate the parallel impedance of 11 + j0 (the presumed resistor) and
0 - j600 (the shunt C) and you'll see that you wouldn't be able to see
the shunt C when making the 11 ohm "sanity check".

Even at HF, measurements aren't nearly as simple as they sometimes seem
they should be.

Hi Matt,
the most broadband VHF / UHF receiving antenna, quite easy to build,
is a discone antenna. Search the web for "discone", you will find what
you need.

>Ohm resistor? 300 is not a standard value. Also, is there any chance
>this resistor is wire wound? Makes an important difference!

It probably is 330 ohm, it wrote 300 ohms just to show in what
order of value it was. It is not a wire wound, probably a bad
quality carbon resistor, but even in the firs case I think it
would only affect if used in series, not if used in paralel
(where the extra inductance would simply put a higher value Z in
parallel to the source)

>Alternatively, the same phenomenon should occur if you put the
>resistor in series. Be careful to maintain ground in all tests.

Yes, the series circuit would also probably work foro estimating
the input Z, but with the parallel it is easier to solder one leg
of the resistor to ground and touch/don't touch the signal wire
to compare both situations.

>Finally, what are you using as an input reference? The signal from
>this same 50 Ohm feedline?

Yes, I just turn to SSB where AGC seems to have much less effect
(if working at all) and "touch/don't touch" the resitor. The
effect on volume is very noticeable. Unfortunately the ICF-7600G
has no s-meter.

>Buy a cheap passive antenna tuner, e.g. the YAESU FRT-7700
>or the one from MFJ Enterprises.

This is just what I wanted to avoid. I just wanted a
better-than-nothing approach that doesn't require retuning at
every band change. Aside, having no s-meter it would probably be
difficult to calibrate the tuner.

Something different would be a pasive preselector. I will
probably buy or make one, but this is a different beast.

>Forget that idea with the resistors.

You will excuse me but I don't see why. It may not be a high-tech
computer-controled impedance analyzer but I just need
order-of-magnitude precision, I don't even need the first digit
to be much accurate.

Thanks for your comments

Yes, I think this must be the case, but even if it varies I think
it will go up/down to double/half or triple/one third, I don't
think (hope not) it goes to 10x / 1/10th. That's why I don't want
to try to perfect-match, just same order of magnitude match

>As the radio's AVC circuits will make up for gain losses due
>to mismatches. Also realize that the receiver's front end
>noise is much less than the amount of noise produced by the

>you can do. A perfect match of antenna to front end would just
>deliver more noise along with signal, and would be indistinguishable
>from a mismatch with the AVC making up the missing gain. I'm
>talking about around 10dB mismatches here.

Well, the case is that I've been playing, among others, with
untuned shielded loops, and they really help reduce interference
by carefully turning them. Unfortunately they also produce very
low signal level, close to the point of not hearing much
difference in background noise when connecting/disconnecting the
antenna. That't why I'd like to gain those extra 5~10 dB by
mathing the receiver to the feedline.

Aside, the ICF-7600G is possibly the best receiver I have had so
far in sensitivity and selectivity, matching, if not improving,
my TS-570-DG transceiver. It is also great for carryng arround.
(I know I shouldn't make free publicity...)

Thanks for your comments

I 've got te answer

I wonder first if dBW depended or not on the QRG below 30 MHz.
It doesn't (excepting that over 30 MHz there is less noise temperature and
often transverter in front of TX showing a 20 dB gain, and this figure is
thus till less).
In addition dBm and co are defined by IARU recommendations where I found all
equivalence dBm-S-point-dBW.

Thanks for your answers but I never imagine that at receive the true power
was so low. I add well a signal report and equivalent in dB or dBW but I
never really make this relation.

3300. carolina windom vs dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-16 15:39:50 UTC
From: Thierry <http>
Message-ID: <4149b3ca$1@news.vo.lu>
Source record: 89421

Hi,

Have you some experience on the air using a Carolina Windom 40m long
compared to a G5RV 31m (100 ft) long...
I have the experience of G5RV but not the Windom yet.
The objective is using them for local qso but also dx in ssb (according to
their possibilities, thus not up to reach JA from ON or maybe via the
grayline, to see..)

I am going to install both (in NS and EW direction) but I really don't know
which is best or if they are really on par.

The Windom comes with 2 traps (1 per segment, as the standard design), a 6:1
balun ended with a coax. The G5RV is multiband too, without traps and uses a
4:1 balun ended with a 10m ladder line (standard design) , then a coax.
There is this already 2 or 3 hardware differences.

Knowing that one segment of the Windom is shorter, does it impact negatively
the radiation pattern with e.g. more sensitivity to QRM or other "defect"
that G5RV doesn't show ?

NB. I could use HFANT or MutiNEC to simulate that but that required to input
all antenna parameters first to design it before ask the program to simulate
its pattern... a field experiment is faster and welcome ;-)

Thanks in advance

Thierry, ON4SKY

Thierry, ON4SKY wrote:
"With -93 dBW for a S9+10 signal at receive, that`d mean that the popwer`d be only P (W) = 10^ (dBW/10) = 0.7 watt?

I`m familiar with received carrier power expressed in dBm. -93 dBW is a number, 30 dB less if expressed in dBm, or -123. This is a strong signal for a narrow-band receiver.

Across 50 ohms, 1 watt is sq rt PR, or 7.07 volts.

93 dB is about 45,000 times, as a voltage ratio, so a received voltagw of -93 dBw is about 0.00016 volts, or 0.16 millivolts, or 160 microvolts.

S9+10dB is a strong signal. So is 160 microvolts. I`ve read that each "S-unit" is 6 dB. S-1 would be 18 dB less than S9+10 db, and that`s a voltage ratio of 7.94. S-1 would be about 20 microvolts, and well above the threshold of most receivers.

Best regards, Richard Harrison, KB5WZI

Hi Thierry,

One application (local/DX) has to suffer at the expense of the other.
YOU have to choose which application you want as first choice.

>I am going to install both (in NS and EW direction) but I really don't know
>which is best or if they are really on par.

This is another choice YOU have to make. What do YOU want to do? If
it is grayline, you cannot do this very effectively with a dipole
going North/South.

Even going East/West will not result in the best if you work stations
mostly in a ENE/WNW Great Circle bearing.

You need to use a propagation program like WinVOA to see what design
you need (dipole orientation that is) and then build to that bearing.
If you build two antennas that are crossed (and even if one is Windom
and the other G5RV); then you will have a suitable solution -
somewhere (even if you drive them both and phase them).

>There is this already 2 or 3 hardware differences.

These are practical problems of construction, not operational results.

>Knowing that one segment of the Windom is shorter, does it impact negatively
>the radiation pattern with e.g. more sensitivity to QRM or other "defect"

Hi Todd,

You want high pass filters for a receiver with the roll-off frequency
set at the lowest end of your listening range. This is usually the AM
band's top end to keep their power out of your receiver's front end.

Low pass filters are for transmitter outputs to reduce spurs and
harmonics (and should be as close to the source as possible).

The Radio Shack 25-1300 Mhz discone antenna is relatively cheap. Not
the most robust, but for an attic may be just fine.

Hi Thierry,

If I may put in my two-cents worth, a dipole is a dipole. The G5RV is a dipole and the Caroling Windom is a dipole. Except for their use on harmonically ralated bands the radiation is the same for each. Any different radiation pattern on harmonically related bands results only from a difference in lengths of the dipoles. The dipole length of the traditional G5RV is 102 feet. If the Windom is cut for some longer length the pattern will be somehwhat different on the higher harmonic bands, but the difference will be rather insignificant.

Roy,

You are right (as per usual). I didn't check the MFJ269 open circuit readings. At 30 MHz, with the N to UHF adapter installed, open circuit Z is 0 & j656. Since my capacitor readings were about 10% less than that, my guess is that the resistor reactances were actually about 1/10th of that (~1 PF). If I remove the N/UHF adapter, x rises to 1389. So, most of the C is in the adapter, which was in place. I think the 12 Ohm data is OK. The capacitance washed out, and it showed a series inductance of 21 nH.

As I said, this is not a precision instrument. Unfortunately, it is less precision than I thought. I hope that somebody with access to an HP or similar instrument will feel inspired to measure some resistors at RF. Meanwhile, I am going to look at some resistor manufacturers web sites.

Tam/WB2TT

Toni wrote:
"---if I parallel a 300 ohm resistor to the antenna input the received signal drops considerably."

Toni says he is not interested in high accuracy, just an idea of what his receiver impeance is. He is on the right track. If two identical resistors are paralleled across a voltage source, each takes the same current. The portable radio antenna is probably a current source due to its high capacitive reactance in the too-short antenna. That makes the voltage out proportional to the impedance loading the antenna.

Forget the .7 vs. .5 of the power vs. volts relations. All you want is a rough estimate of the receiver`s input impedance. Just use common carbon resistors to find which cuts your received level from a weak signal (not to get AVC involved) to about half what it is without the parallel resistor.

Best regards, Richard Harrison, KB5WZI

Why don't you just tune the loop? That would cure the level problem,
and also reduce out of band signals. I do agree with the other poster
though. It doesn't take much to provide a usable s/n ratio on HF. If
the noise level increases when you connect the antenna, it should be a
good enough match. MK

3313. Re: dBW in S-unit and power strenght

Newsgroup: rec.radio.amateur.antenna

Message-ID: <cicr9q$25b$1@sparta.btinternet.com>
Source record: 89434

At HF it's all very simple.

To summarise -

The S-meter is essentially a 50-ohm power or wattmeter.

It is correctly calibrated with a 50-ohm signal generator with its open-circuit volts set to 100 microvolts. The S-meter should then read S9.

Therefore, at the standard S9, the input to the receiver is 50 microvolts across 50 ohms, corresponding to a power input of 50 picowatts.

The standard S-unit = 6 dB.

So for each change of one S-unit the input voltage halves (or doubles).

At S-zero the input voltage is 50/512 = 0.1 microvolts, which is roughly equal to the the internal noise level of a good receiver with a bandwidth of a few KHz.. Theoretically this is about the noise level you should get when the antenna is disconnected.

At S9 + 40dB the input voltage is 50*100 microvolts = 5 millivolts.

Some S-meters may indicate as high as S9 + 60dB. The input voltage is then 50 millivolts which is about the overload point of a very good receiver.

So the whole scale is calibrated logarithmically, with S9 being about half-way along it, and with 54 dB below S9 and 40 or 60dB above S9. The input voltage range is from from 0.1 microvolts to 5 or 50 millivolts.

==========

However, all meters have indicating errors. The problem arises because of the difficulties and great expense in designing and manufacturing receivers with an agc meter system which can accommodate a signal level range of 54 + 60 = 114 dB. Economics invariably rules the roost.

(It helps to have very high receiver gain and attenuators at or near the receiver input.)

Fortunately modern receivers all tend to have errors of the same sort and sign. So amateurs using different manufacturer's receivers will exhange very similar signal strength reports.

These errors congregate at the very small signal end of the range. Meter calibration begins to go wrong at around or below S4 or S5. Meter readings of, say, S1 or S2 may actually be appropriate to power levels of S3 or S4. A meter reading of S-zero may be appropriate to a power level of S2 or S3.

That is, at very small signal levels the S-meter underestimates signal power level. But it's not of great consequence. At HF, to which the foregoing applies, signals are usually below the noise and QRM levels anyway.

Reg.

Taking one band with another and one direction with another, the difference between a Windom and G5RV will be entirely undetectable.

They will both have somewhat poorer performance than a simple random length dipole of about the same length and height fed over a random length, high impedance, any Zo, open-wire line.

Following the study you have given to the subject, you may be disappointed at the responses to your question, But you did ask.

And there's no reason why you should be deterred from experimenting with either or both types of antenna. You will then be at least as wise as us Old Wive's.

If you should like playing with just a few numbers then amuse yourself with small programs DIPOLE3 and ENDFEED. Download from website below in a few seconds and run immediately. They provide lots of data but the most important thing is the single number - radiating efficiency!

Anything which repeats itself is amenable to Fourier Analysis.

If there's a once-only event then Heaviside's Operational Calculus is appropriate.

It's not more difficult. It's just a matter of getting used to it.

All radio people suffer from delusions of measuring accuracy.

RF power measurements are the most inaccurate of all.

The accuracy of measurements are a function of the instrument user.

They who attempt to grasp support by stating the manufacturer's type number of the instruments used are most in need of the self-confidence it falsly generates.

Either that or the statements are gratuitous adverts.

How cynical can one get at this hour of the day?

Thanks for all comments.

I did a mistakle in my specs because they are no traps on the windom (I confused with W4DZZ).

In fact I thought that both designs being wire antennas of almost the same length, they 'd display the same radiation pattern at a few percent.
But I was focused on the shortest segment (1/3) of the windom and wonder whether it could cause or not additional problems or display drawbacks compared to a real dipole...
In all case I will test it in 2 weeks.
Problem with dipole3, the influence of a shorter segment is not taken into account. I don't know if that could be important, probably not much, but it 'd have been interesting to add some additional parameters like the length of each segment and the tilt of the tilt too to get a more accurate result.

Addition:
My believe is founded. I just find some radiation patterns and comments in the ARRL antenna book ch7-8. The windom is much more omnidirectional than a dipole. They say that "the system (windom) takes advantage of the asymmetry of the horizontal wires to induce current onto the braid of the vertical coax section.... The radiation pattern... tends to fill in the deep nulls that 'd be present ... if horizontally center fed".
globally they consider that the windom give better results due to the omnidirectional pattern or so than a true dipole.
Anyway, if I have the courage I will try to simulate the windom in Multinec.

Thanks for the help
Thierry, ON4SKY

Good idea, about simulation, I will try to create the windom design in
multiprop or hfant (I know the one of the dipole) and then run the voacap to
see what the matter.
FYI here is the pattern at short distance of a G5RV, 100W, tight EW,
http://www.astrosurf.com/lombry/Radio/soft-multiprop-on-la-12.gif
The windom should be more omnidirectional.

Yea. I've tried both. They both are sort of lame compared to a normal coax fed dipole for a given band. I agree with Walt that a dipole is a dipole as far as pattern for a given band...The difference is how much power actually makes it to the antenna to be radiated. This is what separates the mediocre from the better.
If I wanted to work dx, I would use neither of those antennas. But you don't mention what band you want to work dx...The lower the band, the better the standard coax fed dipoles in general. But on the other hand, the lower the band, and the better a good vertical would work compared to the dipole. :/
Anything can work dx on the higher bands unless the radiation angles are way too high. If you want all bands with a single wire, I would use the standard dipole cut for the lowest band, and feed with ladder line and a good tuner. Or no tuner with the Cecil method...Myself, I prefer paralleled dipoles fed with a single coax. Don't need a tuner, and the efficiency is high. The G5RV and the common storebought windom both have fairly lossy feedline systems for my tastes. And the windom is prone to common mode problems, etc...I don't like an unbalanced antenna unless it's a last resort. MK

Ok Mark, for sure for DXing a dipole or a windom is not a beam...
From europe in SSB and barefoot (100W in SSB), with my G5RV tight EW I reach FY, PY, midwest US, VU, 4S, UA9J,C, RA9 artic, central africa. Hard to go farther bu these days of SSN decreasing.

My objective is Dxing first as for local QSOs this is not a problem to get S9+.
I know very well that DX performances will be more than limited, all the more in SSB, but this is a temporary solution waiting for a small beam 3-or 4 ele.

============================

Gary, we have heard the news over here about the devastating Hurricane Ivan. We get them here at about 1/2 strength of yours only once every very few years. And even then it's only over a relatively small area.

If you can't understand what I am wittering about then its due either to the storm stress you are under or because you are one of those suffering from delusions of accuracy. In your case I prefer the former excuse.

I hope your generator started up OK and that you and your family suffer the bare minimum of danger and damage. At least communications between us are still intact. My best wishes.

Reg, G4FGQ

Gary,

I saw an interesting curve at a resistor manufacturer's web site. It plotted resistor error as a function of F(MHz) x R(Meg) for 1/4 W carbon resistors. To make a long story short, the resistor error will be about 20% where the Megahertz x MegaOhms = 1. That means the resistor value will be 1/ Frequency. So, at 30 MHz, the resistor will be in error by 20% if it is bigger than 1/30 =.033 Meg, or 33K. That, I believe ignores capacitive effects. Personally, I have never tried to put RF through a resistor bigger than a few hundred Ohms.

It occurs to me that you can ignore capacitive effects if you make all resistors identical. For instance, if you want a 3:1 divider make the series resistor 10K, and the shunt resistor two 10K resistors in parallel. Of course, you will need a high impedance load on it. Let's see if anybody shoots this down.

Tam

> and the Caroling Windom is a dipole.

Hi Walt, I don't know if you know or not, but the Carolina Windom
is designed for the vertical section to radiate so it has a
radiation pattern which is a combination of a dipole and a vertical.

And not so curiously Trc = 1 MOhm ï¿½ 1 pF = 10^-6
F = 1 / T
F = 1 MHz
perhaps the product rule should be:
Megahertz x MegaOhms x picoFarads = 1

The 20% error is, of course, simply the rolloff response at the RC
inflection point described by 1/Trc.

>Let's see if anybody
>shoots this down.

Hi All,

I think chipping at the clay feet of saints is more appropriate
metaphor.

What is the saint? The RF response of the resistor. It should be
suspect right out the gate. Being suspect, you employ the
conventional techniques already evidenced even by the cheapest Power
Meter builder (MJF) by swamping the stray capacitance with series
capacitors (paralleling the resistors). One capacitor is either
variable, or further paralleled with a trimmer. The saint is also the
unspecified requirement: is this divider BEFORE OR AFTER the detector?

If before, and thus subject to RF, the simple RC compensated divider
has served for eons. If after, and thus subject to only DC - who
cares? The one clay foot of the discussion.

The other clay foot of the discussion is that for placement before OR
after the detector, ALL ratios are post-hoc determinations (in other
words, design with variable components fully expecting you WILL be
wrong). Further, ALL descriptions to this point have been of
normalized levels. With the RC compensated divider, you are throwing
the knee if rolloff into lower frequencies so that ALL frequencies of
interest reside on the same slope. Hence the common "calibration"
procedure has you adjust the resistors for the low frequency readout,
and the capacitors at the high frequency readout. This "calibration"
is simply distributing the error so that it doesn't accumulate
outrageously.

The greater challenge is how do you know how much power you are setting your meter to read? Compounding errors are common in RF.

I'm sure this has been answered before. Can I mount a 2M halo on the same mast as a 2M vertical (jpole) without any adverse affect on one another? If so, is there a certain space that needs to be between them? Thanks for any help.

Hi OM,

They have different polarizations, so, in effect, they reside in each
other's null. On the other hand, the JPole is intrinsically Hi-Z and
can be disturbed by changes to its counterpoise (the metal beneath
it). However, once you tune them both up, they should live as benign
neighbors.

Pretty much so, yes, as long as there's a reasonable vertical
separation between them. The halo's emission is horizontally
polarized, with a deep null "overhead", so it won't tend to "notice"
the mast or the J-pole. The J-pole's radiation is vertical, with a
deep null below, and the halo will have little effect on it.

I've got a Copper Cactus 2m/440 J-pole at the top of my mast, with an
aluminum-strip halo mounted about 6" below the bottom of the J-pole's
matching stub, with the halo's closest (grounded) side being about 3"
from the mast. I haven't run any field-strength studies, so I can't
say for sure, but as far as I can tell there haven't been any
significant changes in my ability to work local repeaters or simplex
stations on the J-pole, and the halo's sensitivity seems quite
acceptable for its type.

Hi Thierry:

The only draw back of the off center fed dipole is the possibility of introducing radiation from the feedline which can make for R.F. in the Shack if not properly acconted for , it also makes predicting the radiation pattern a little skewed to the long end of the dipole. I Use two off center fed dipoles (miss nomer windoms) here one is cut for 40m long the other 20m long the 40m long one is fed with a 4:1 balun and 75 ohm coax the 20m long is fed with 300 ohm open wire line to a tuner. both antennas do a good job for me. I do mostly causual dxing (but as one poster has already said you'll have to decide which propagation mode you are seeking if grayline put up a vertical or other lowangle radiator for 80meters.) They are mounted at 90 degrees to each other. I've been able to work lots of dx on these antennas .. I had two g5rv's up prior to these and from a pure operational veiw point find them a little better at my location.

hope this is of some help.

Normally done with a noise bridge.

Am scratching my head what to do, if there is no noise bridge....

Indeed, all the interest of the thing..., hence my question.
But I wonder also about the QRM pick-up along this vertical segment...
I will have the answer in two weeks.

For sure the location add a bias factor, soil, rock, sand, trees, etc affect
the radiation pattern, all the more that on my Windom the coax segment will
be at 50% in trees... although the ladder line of my G5RV was in the air,
off trees...
Anyway, I will have the confirmation in a few weeks.
If results are "unattended" I will post a new msg.

3340. Re: dBW in S-unit and power strenght

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-17 13:57:02 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cieqfe$pe7$1@hercules.btinternet.com>
Source record: 89461

The distortion in S-meter scale-shape at very small signal levels, below about S5, could be corrected very easily just by changing scale markings. The meter scale would then end at about S2 instead of S-zero. And the meter would indicate correctly as a wattmeter over the whole length of its scale.

But S-meter manufacturers are reluctant to do this. They consider it would spoil the linear appearance of the scale at the low end and so lose customers. How foolish they are!

Keen radio amateurs can change their S-meters into accurate instruments over the whole scale just by scraping off existing scale markings and re-calibrating with a fine-nibbed pen and black indian ink.

But on second thoughts, to save yourself the trouble, when using the meter it's even easier just to visualise and remember where S3 should be marked on the meter scale.

> And not so curiously Trc = 1 MOhm • 1 pF = 10^-6

I think the curve ignores C, and is based on skin effect only. There is no explanation for the data.

> F = 1 / T
> F = 1 MHz
> perhaps the product rule should be:
> Megahertz x MegaOhms x picoFarads = 1

Go to http://www.xicon-passive.com/resistor.html and click on CC. There is also info on resistor performance vs frequency in the W6SAI book. He shows curves for 5 different carbon resistors vs frequency without identifying the resistor values. As a gross average, they show about 50% error at 15 MHz.
>
> The 20% error is, of course, simply the rolloff response at the RC
> inflection point described by 1/Trc.

The curve goes from 0 - 100. I arbitrarily picked 20 % as being a point where there is apreciable error.

So true. I notice the series C in the Kenwood meter is variable.

I have used 160M Carolina windoms for the past 5 years or so and have found them to be really good performers. The higher you can get the vertical element off the ground the better (I have had good results with it only 20' off the gorund....Radioworks recommends more). I have never modeled it, nor had experience with G5RV, but compared to a half wave dipole at similar height, my "impression" is that it performs at least as well, probably better, plus multiband. Beward you will need to use a tuner with it, and if you are running legal limit, be careful of your SWR's as you can burn out the balun or RF choke (they are not traps). There has been a lot of debate about this antenna, but I can tell you the 160M version works quite well on all bandsl.

The original windom of the 1920's had a single wire (vertical)
feedline. The Carolina Windom as sold by Radioworks has RF radiation
from the feedline which is a deliberate design consideration of this
antenna; it has a vertical element (the piece of coax hanging off the
balun) which is designed to radiate,. and which creates the low angle
lobes. The RF radiation is STOPPED at the RF choke which is at the end
of the "feedline". Then YOU feedline connects here and essentially
does not radiate.

There is alot of information on this antenna at
http://www.radioworks.com/, some of which contradicts some of the
mythology which appears in the NG's and reflectors..

Why would QRM be a problem ? The beter the antenna the more signal it will pick up. Maybe you ment QRN (noise) instead of M (undesired radio signals) ?

Nice tutorial, Reg I printed it out for ref.

...however.
The 2M rigs I've measured (3) are WAY off. The +20 +40 and +6o are usually also around 6dB plus or minus 3 or 4 dB. I measured my TS-830s and it was not very close, and my 706, but don't recall the results and haven't done the TS 2000 yet.

While I will not debate or dispute the origional S-meter meanings, I would have to say there is almost no rig that follows that calibration. I have measured a few low band rigs and several vhf/uhf rigs. The low band units seem to be somewhat more 'calibrated' than the VHF and above rigs but most are usually way off. From my observations and the write ups in QST the S-meter and the 50 uV and all the 6 db per S-unit should not even be spoken of .

We need to kill the idea of the s-unit being 6 db or anything at all. They are just numbers on an uncalibrated meter on most receivers. You might just as well mark the meter from 0 to 100 and go by whatever number the meter is showing. The meters are not linear, log, or any combination that can be depended on from one brand to another brand. Even changing bands on the same receiver will usually change the 'calibration' of the s-meter.

3349. Clemens match modelling

Newsgroup: rec.radio.amateur.antenna

Hi,

I've been trying to model the Clemens match (it's a sort of off-set gamma match) on NEC (specifically 4NEC2 and NEC2D). I find that the addition of this reduces the calculated antenna gain by about 2dB. If I model it using MMANA, the gain is unaffected, which is what I expect, Has anyone had any experience of modelling this sort of match ?

>explanation for the data.

Skin effect would tend to increase resistance which contradicts the
trend. As for explanation:

From "Electronic Components and Measurements," Wedlock and Roberge,
1969:
"At high frequencies the performance of a resistor will depart
from Ohm's law because of stray capacitance and lead inductance."
[pg. 77]
There is an identical curve to your reference shown in Figure 7.4,
same page:
"Change in resistance of a ï¿½ Watt carbon-composition resistor as a
function of frequency. Frequency in MHz times resistance in
Megohms"
In Chapter 18 "RF Impedance Measurements":
"Such behavior is often termed stray capacitance or stray
inductance. Because these effects are usually undesirable and
serve to limit the high frequency performance of components, they
are also called parasitic effects." [pg. 276]

However, my expression of this being rolloff was too simplistic as the
curve does not follow the typical 10dB/Decade characteristic. Rather,
it shows a 6dB/Decade+. Some of this may be accounted for in lead
reactance, but at the Megohm scale this is inconsequential for
conventional leads.

Gamma-type matches consist of a small loop containing a source. This type of geometry can be a problem for NEC, and often produces the symptom you describe. You should have the progam report the average gain (see the NEC documentation on the RP "card"), and use it to correct the gain, unless you can rearrange the loop to get the average gain close to 1. MININEC-based programs don't have this problem with small loops -- they have other problems instead.

EZNEC users will see the average gain reported at the bottom of the main window after every 3D calculation, and its meaning and use described in the manual. However, note that EZNEC normalizes the correct average gain to a standard value of 1 with or without ground, while NEC will report a value of 0.5 (or 2, I don't recall for certain) when everything is ok but a ground is present.

I'd rather have the coax fed dipole over the windom any day though...I
bet many people would think it's a beam , the way it will most likely
trounce the average windom.
I tried one "windom" at a field day against a coax fed dipole. The
dipole won by 2 s units in any direction. Thats about what you would
see going from a coax dipole to an average beam...:/ Or by changing
from 100w to 500w-1 KW...

>
> My objective is Dxing first as for local QSOs this is not a problem to get
> S9+.

If it's working local, why would it not be working dx ok? Why the
change to an antenna which basically will be the same, assuming
element lengths are fairly close for a given band, barring any changes
in feedline efficiency? IE: I assume you are going to switch from a
G5RV to a windom....
Thinking about either one of those antennas makes me want to take up
golf...
I don't like either one. It's no secret though....:(
The only thing the G5RV has going for it, is it is nearly a EDZ on
20m. But it's a reduced efficiency version compared to one fed in a
normal manner...
Coax to a choke to ladder line as a feedline is no way to live for a
serious dx'er who wants most of his power to actually be radiated by
the antenna element...The windom is not much better in this
regard....Or at least the ones I've seen.

> I know very well that DX performances will be more than limited, all the
> more in SSB, but this is a temporary solution waiting for a small beam 3-or
> 4 ele.

You still don't mention which band/s though... There are fairly simple
wire antennas much better for dx than the usual all band compromise
wire antenna. IE: extended double zepps, phased parallel dipoles, etc,
etc. I would use something along those lines if I wanted to dx say 20m
or up...If you want to dx 80/40, you might consider a bobtail curtain
or variant, or a good vertical. Trying to increase the dx potential by
changing from one semi lame antenna , to another semi lame antenna
strikes me as counterproductive. But, it's your yard and $$$.... :/

Hi Richard, I haven't been able to keep up with this like I wished because of
that pesky Hurricane. If you put the detector circuit before the voltage
divider, then the resistors see DC which they are a lot happier with. The
detector diode will have to be 700VDC PRV rating, and the filter cap. will have
to be sized properly.
I guess the diode will have some frequency dependent properties, but as long
as it still acts like a diode, and the forward bias drop is around .6V it ought
to work. This looks like good alternative to frequency dependent resistors.
What say you?

FYI
I have used either 470 or 510 ohm carbon comp resistors way back when as 20dB probes for a sampling scope and Spectrum analyzer work. If I recall, they were quite comparable to the scope's regular probes for pretty fast digital signals.
I would, however, get nervous with the high values stated / needed here. At first I was thinking I'd series-up 500 or 1K resistors if I had to do this, but then strays start to become significant as has been well discussed.

If you have the equipment, I like the frequency response / sweep idea. This way you may even be able to adjust the compensating caps for best high freq (10M) response. You could also use the calibrator on most good scopes to start out....

Hi Gary,

For a diode, the 1N4007 is rated at 1000V. However, you have to design with Peak voltage in mind, and then add 50% safety factor for good design. Further, feeding a capacitive filter requires you DOUBLE the PIV rating. All in all, this suggests your design choice should tend toward the divider before the detector. Then the question becomes, do you want a peak reading meter, or an averaging meter? A peak reading detector (AKA Clamp) will lightly load the divider whereas the averaging will load it more (and ruin any fixed divider ratio - which returns us to the variable component to be designed in).

Hi Steve,

This would probably improve the parasitic capacitance while increasing
the parasitic inductance. Off hand, I think the inductance would
probably be tolerable in the HF.

A 1N4007 or any other silicon power diode is a poor choice as a
detector, for several reasons. The first is the large shunt capacitance.
The second is the long reverse recovery time, which makes silicon power
diodes look like a resistor rather than a rectifier at HF. High voltage
diodes like the 1N4006 and 1N4007 contain an intrinsic layer to increase
the voltage breakdown. This dramatically increases the reverse recovery
time to the point that they can be used as PIN diodes at HF.

Schottky diodes don't have the reverse recovery problem, but power
diodes still have a lot of capacitance (and reverse leakage current).

Only a signal diode should be used as an HF detector. If you can't find
one with a sufficient reverse voltage rating, you'll have to use a
divider of some sort.

Hi,

160m long 20' high ? That must be interesting and u had to confirm over 100 dx with such a length...
I very well know these problems of SWR etc,and many others. I am an OT you know,... Hi! I learnt the lesson in the past in experimenting live a bad SWR... youth errors as one tells... but interesting because I never more forget the lesson, like many others in experimenting myself.
With some respect it it far better to be chocke a second and get a little blister due to a SWR over 5:1 using a kW amp that having hours of theory... because you cannot fix your idea on concrete things.

For the rest, of course the heigth (and length) are VERY important, all using a dipole or windom all work fine or almost from 8m high and 20m long and up. Below your radiation pattern is seriously affected compared to the ideal solution (say 2-lamba over 12m high). And you feel that very well when trying to call CQ DX and even simple CQ up to 5000 km away.
To get an idea simulate these specs in modeling software like multiprop that use a VOACAP engine, or even nec, hfant and others.

See my best site for detail.
Thanks for the help.

No ! I speak of QRM, made made, due to vertical segment (vertical polarized
I believed) that, i thougth, 'd pick up more QRM, in the same way as a
vertical antenna coupled to a dipole tight horizontally e.g..
But in this case it doesn't as this is a common-mode choke balun ; there is
no RF radiation form the coax.
In all cases I will see the result in the field very soon, adn could
appreciate both designs (dipole vs. windom).

Hi,

No. For a true dipole and get a low impedance etc I prefer by far the ladder
line; The coax is easier but is less performing
This is not much difference, but measurable. I always prefered the optimum
solution.

> bet many people would think it's a beam , the way it will most likely

Ok. I will see but 2 S-unit are much. What is sure is that the radiation
pattern of a carolina windom is next over a dipole :
http://www.astrosurf.com/lombry/Radio/ant-carolina-windom-radiation-pattern.gif
it is much more omnidorectionnal what could explain is overall better
performance.

Local is not DX. High takeoff angle vs. very low. This is a huge difference
if you check your receive strength signal.

In general, coax fed is usually the least loss for a single band
dipole. The system is over 95% efficient on hf. Ladder line is low
loss, but people usually use a tuner, so it ends up being slightly
lossier than the coax fed overall. If you use no tuner, the losses
could be pretty comparable to coax fed. The losses using a tuner can
be fairly low if you are careful to use least the inductance.
As far as I'm concerned, feeding a 50 ohm antenna with 50 ohm
feedline, from a 50 ohm radio is the optimum solution as far as
efficiency is concerned.
>

> >
>
> Ok. I will see but 2 S-unit are much. What is sure is that the radiation
> pattern of a carolina windom is next over a dipole :

Would be appx the same if the wires are the same length. But that
could vary if the antenna is used on higher bands, and the wires are
longer in wavelength.
> http://www.astrosurf.com/lombry/Radio/ant-carolina-windom-radiation-pattern.gif
> it is much more omnidorectionnal what could explain is overall better

In the real world, I doubt you would notice much directivity with any
of them, except maybe on the highest bands.

> if you check your receive strength signal.

Yes, but why would either be overly high angle? In general, this will change more due to height above ground. Changing from different types of wire antennas will do little to change that if all are at the same height. The only exception I can think of is using a long 80m dipole or other antenna on the higher bands like 10m. I've seen cases where the t/o angles were quite high, but that's kind of a special case. Unless you get them high in terms of wavelength, none are going to be real good at low angles. That's why I recommend a vertical on the lower bands, if you want dx. MK

Are you sure you want a phasing line? I think you mean a series
transformer...
Yes, rg-59 should work ok for fairly high power. You would need appx
22 ft worth for 40m...RG-59 as a transformer section would probably be
ok to maybe a KW or so. If you plan on some manly legal limit 8877
loudenboomer, you might consider the rg-11...:/ MK

> > > I'd rather have the coax fed dipole over the windom any day though...I
> > Hi,

I have a last question about the vertical coax of the carolina windom.
Imagine that the balun I have is a common mode choke balun (I am not sure
and I asked details to the manufacturer)
like on this drawing :
http://www.astrosurf.com/lombry/Radio/ant-carolina-windom-dwg.gif

Without speaking about heigth above ground, QRG and length, how do we
explain the more or less omnidirectional pattern against a dipole, see
diagram at
http://www.astrosurf.com/lombry/Radio/ant-carolina-windom-radiation-pattern.gif
if there is no radiation from the coaxial ?

In this case where does come from this 360° gain over a dipole that shows
"only" 4 main lobes in azimuth?
If the common mode choke is used, the diagram 'd be similar to a dipole, no
?

Thanks for comments

A quick and dirty I learned for putting up temporary dipoles. Mount the
insulator a good bit short of the end of the antenna. Then when you prune
for resonance you will not have to keep removing and reinstalling the
insulator.

3373. half-wave dipole in the forest

It is designed to radiate some vertically polarized energy so it
is also designed to receiver some vertically polarized energy.
That would render the Carolina Windom virtually useless at my QTH.

The vertical coax section between the impedance matching device at the
feedpoint and the RF choke is designed to radiate and it does. The
coax between the RF choke and the source is designed not to radiate.

I live in the forest, and use a couple of resonant dipoles hiding in the trees. I have no problems at all. Once, during our ice storm, one of them came down when a tree broke off and fell. SWR is fine, and get good signal reports.

Go for it.

Only caviet-- You need at least a general for 30 MHz, or below, but
the absorbsion of rf at those freqs is minimal, tho the HEIGHT, at lower freqs
for a good pattern (for long distance) might be a problem. But , say on 80-40
even at around 20 foot elevation, can work reliably several hundred miles!
20 and up meters shouldn't present much of a problem, and at 6 and 2 meters yagi
be best bet, but relatively small size. Have fun- Jim NN7K

I have several wire antennas strung between trees, and found that even #14 or #16 wire with black or blue insulation at 50 feet is invisible against the trees, and almost invisible when viewed against the sky. What sticks out is the feedline, if it is hanging in the clear. You want that coming down next to a tree. You really don't want contact between the wire and branches. However, my 75m antenna goes through branches at one point, and it seems to be OK. Stay away from white, yellow, or red insulation.

Yes it will "work", but the 40 meter dipole (and depending on the elevation of your attic, possibly the 20 meter dipole as well) will probably function as high angle radiators. If NVIS communication on 40 meters is your goal, you may view this as a good thing. But NVIS communication on 20 meters isn't common, so expect mediocre performance on that band if you don't have at least a 2 or 3 story house.

A rule-of-thumb that I use is: For a resonant half-wave
dipole, the voltage at the ends is *about* 20 times the
feedpoint voltage, nothing to be sneezed at.

Hi Frank,

This is dreaming in technicolor and surround-sound. I post with my
full name and address in the clear and as a consequence never "see" as
much as one spam in a month. Certainly my filters kill up to 10 a
day, but as I said, I don't "see" them - takes all of two or three
seconds to automagically wipe them out on start up or take them out
like a bug-zapper when they straggle in.

I get far more spam on my business account with my address registered
with government agencies. I have to add one or two new spammers to my
kill file there each week and that currently outnumbers my killfile
here 7:1. The spam that I do see here isn't even addressed to me.

==========

Yes. All falling trees make a sound. But if there's nobody to hear it who cares?

But this business about 100 watt transmitters causing forest fires is exaggerated. Even if there's a conjugal impedance match between a dead leaf and the transmitter there's little to worry about even when its not raining. And the density of foliage is hardly likely to allow flames, should they occur, to leap from one leaf to another.

The climate and type of tree involved is, of course, of some consequence. Deciduous trees and those found in South American and Indianesian jungles can be disregarded from this discussion,

If you should live in Australia, the home of Eucaliptus trees, during the dry season, and it's always dry, there is a one in 100 million chance of a tree catching fire by radio. Always supposing by some remote chance it hasn't first been struck by lightning.

Eucaliptus trees positively enjoy fire. They depend on it to propagate efficiently. This may be an unfortunate trait insofar as kangaroos and wallabies are concerned but alligators are quite happy with the way things have been arranged. The Aussies themselves take care not to build their houses too near to eucaliptus plantations. The Abbo's, with their 50,000 years of experience, radio or not, are quite happy and sensible enough to leave things as they are.

The USA has wide variations in climate and tree population. Thoughtful citizens ought to concentrate their minds on hurricanes, twisters, atmospheric pollution and gun laws. 100-watt transmitters and G5RV's can look after themselves. ;o)

I assure you we are concentrating very carfefully, Reg! Last week we had about 20,000 gun laws on the books, counting all federal and state laws. This weekend we have one less federal gun law, and soon there may be less. When free people use their minds instead of letting foolish emotions be their guide, the concept of restricting firearms from law abiding citizens is one of the first things to go.

Btw, so far my dipole hasn't set the pine trees on fire, or been torn down by a hurricane, despite three attempts by them so far this year ;-)

73,

Jack

Hi Jack,

The D.C. sniper (a known non-law abider) got his firearm from non-law abiding citizens out the back door of a local gun-shop here. Foolish emotions had nothing to do with their inability to account for several hundred missing guns they just shrugged off as bookkeeping discrepancies. Clearly they had more guns than necessary to stay profitable. Imagine how long your supermarket would stay in business at that kind of employee pilfering rate.

Now, if we bring the foolish emotion issue into it, then Mr. John Allen Muhammad, clearly an emotional person, could now simply walk up to the counter and get more bang for his buck. And if denied, I suppose he would have had to pay more at the back door.

James D. Martin,
James Buchanan,
Kumar Walekar,
Sarah Ramos,
Lori Ann Lewis-Rivera,
Pascal Charlot,
Woman shot, wounded,
13-year-old boy wounded,
Dean Harold Myers,
Kenneth H. Bridges,
Linda Franklin,
37-year-old man shot,
Conrad Johnson,
killed or wounded between October 2 and October 22.

Another foolish, emotional personality that appeared before committees to argue that we retain the prohibition against assault rifles was Reagan's Press Officer James Brady. One may say he is emotional simply because he survived being shot (the alternative is being un-emotionally dead).

Well, let's just mark it up to the dispassionate tenor of the Republican Guard who have over the years jettisoned Reagan's mandates as easily as they shrugged off the prohibition against assault

weapons. The Republican Guard has even offered laws to reduce the liability of the local gun shop and emotional others like them that whine they are too hard pressed by rational laws to balance their books or lock their back doors. The example of the Russian school debacle where the collapse of rational law has seen plenty of assault weapons were available makes the Columbine massacre seem like a Saturday afternoon picnic.

"In countries like the Untied States, it's
perfectly legal for members of the public
to own certain types of firearms. If you live
in such a country obtain an assault rifle
legally, preferably an AK-47 or variations"

Exactly! If one advocates disarming *law-abiding citizens*,
one is siding with the *non-law abiders*. Advocating disarming
non-law abiders by creating laws that are only obeyed by law-
abiding citizens is ridiculous. We might as well create a law
making it illegal for hurricanes to hit Florida.

Hitler, Mao, and Stalin all supported strict gun control laws.
If one likes gun control laws, some of the most severe will be
found in Castro's Cuba at the present time. So Richard, if you
don't like the second amendment and want to feel really safe,
simply move to Cuba. :-)

Hi Cecil,

it is well what i though, but in my case this is a Carolina Windom like on
this drawing
http://www.astrosurf.com/lombry/Radio/ant-carolina-windom-dwg.gif

The balun is attached to the wire and there is no segment above it. the coax
enter the balun and the otehr side goes to the TX
hence my question. And is this design still a Carolina Windom, excepted the
segemnts of 1/3 2/3, it looks more to a hybrid between the dipole and the
Windom... isn't it ?
And on this model, if it uses a choke balun (what is not sure) the coax 'd
not radiate RF, othewhise of course if radiate much, like an vertical

What you have is the standard Off Center Fed antenna. A true Windom is fed with a single wire about 1/3 the distance from one end. Many are calling the OCF antenna a Windom which it is not. The OCF antenna is often called a Windom by mistake. The Carolina Windom has about 6 meters of coax that is vertical below the horizontal part and then a common mode choke. The vertical is suspose to radiate some signal for DX and the horizontal is for a higher angle of radiation for the close in stations. I don't know if it actually works this way in practice , but that is their selling point. Here is a URL for the Carolina Windom.

Hi Richard, what's your point here, that more gun laws would deter crime
against gun stores? Not! Stolen guns don't react to laws making them illegal
in the first place, and neither do criminals who can smuggle tens of
millions of pounds of contraband and aliens int the country every year have
any problem, now or ever, obtaining firearms. Same of course goes for the
Ur-a-Peon's who have successfully disarmed their sniveling subjects as the
rate of violent crimes against them skyrockets. More police-state control,
such as you called "rational law" must be required for them, since disarming
the law abiders did not stop the crime waves.

You don't know anyone or any store that makes such illegal sales in your
city, and neither does the BATF, who harass gun store owners about their
bookeeping more than the NRC watches hopsitals to keep track of their
dangerous radioactive materials.

There is more emotion than you will hopefully ever know, than if the life of a loved one was taken because they were too timid, (too emotionally irrational) or too restricted in the ability to protect themselves from a common or uncommon criminal, who uses firearms as a tool of their trade, irrespective of any gun law ever enacted now or in the future. Don't confuse free speech of Jim Brady with our right to prevent getting shot in the head ourselves. All the cops and secret service carrying automatic weapons and trained to spot and actually prevent such attack from succeeding failed. How in God's name do you think anyone could be protected? Maybe your Ted Kennedy who's armed bodyguards surround the scotch-reeking murderer 24-7 as he lobbys for the disarmament of all law abiding citizens?

The collapse of rational law? My friend, you mistake the iron fist of martial law and governmental murder by edict that ruled the Soviet Union for rational law?

The world is at war (or will come to that relaization as they die in sufficient mass numbers) against the nation of islam, who is sworn to a new level of their timeless hatred for all things rational and peaceful. What happened in Russia is an act of that war, and does not reduce to technical descriptions of the tools used to carry out the attack.

In two recent school shootings in America, it was a teacher in one case and a student in another that ran to their cars, and retrieved legally owned firearms that enabed them to stop the killings and subdue the attacker! No police force, not even the iron fist of the former iron curtain could *ever* respond to a crazy person trying to commit mass murder faster than an armed citizenry can. Count your blessings that you have always lived in such an armed and peaceful citizenry, with citizens who will step up to the plate to defend your miserable and pathetic existance that relies on the bravery and good citizenry that you lack, and would save you from the attack you spend your life trying to prevent them from being able to do for you or their loved ones. Just don't call yourself a citizen, not in my Country.

>
> "In countries like the Untied States, it's

That's really sad, and I liked you a lot more when I thought you could keep such drivel from a good argument. Surely you don't believe that Al Queda pretended to be planning anything now or later, that would rely on compliance with laws to accomplish. I am offended by your comment that our government approves of Bin Laden in any way, or does anything to make it easier for him to murder Americans. It offends the sensibilities of all humans in fact.

>
> 73's
> Richard Clark, KB7QHC

Try to pay attention to who the enemy is Richard. It is not lawful American firearm owners who would gladly add you to the list of terrorist organizations if you persist in subverting the rights both enumerated and not enumerated by the Constitution. That you may continue to live as a free man while actively subverting our Constitution is a priviledge that I wish you did not have, but hopefully you are educable before your old age renders that possibility moot.

Hi Jack,

It is already been LONG documented:
" Bushmaster Firearms Inc. of Maine will pay $550,000, all of
which is covered by its insurance policy. And Bull's Eye Shooter
Supply, in Tacoma, will pay $2 million, the largest settlement of
its kind by a gun dealer, the Brady Center said."

I would pause to add that the "Brady" of the Brady Center has already
been dissed by the Republican Right Whiners. Clearly they would
prefer that Bull's Eye paid nothing and perhaps give Bushmaster a
rebate. And if Brady hadn't taken a bullet for Reagan, what kind of
spin would they have to offer? A marksmanship medal for Hinkley?

"Federal agents traced the weapon used in a number of the
shootings, a .223-caliber XM 14 Bushmaster rifle, back to Bull's
Eye."

The linkage was proven through target practice shells obtained at the
sniper's former address - HERE locally.

"The shop had problems for several years. Records show that Bull's
Eye could not account for the sales of 238 weapons"

"Its security was so abysmal that it appears that a 17-year-old,
Malvo, was able to stroll into the store and stroll out holding a
3-foot-long assault rifle," Lowy said. "And Bull's Eye didn't even
know the gun was missing until the police called several weeks
later to tell them it was found in the trunk of the snipers' car."

Copyright ï¿½ 2004 The Seattle Times Company

Let's see, you cannot catch a kid walking out with a 3 foot assault
rifle every day of the week for a year (we will skip holidays and
weekends when they are more diligent). Yeah, right, that's how it
happened! Shoplifters every day for a year and no one notices it at
the till, or in the records, or in the stock room. Clearly a society
of profitable retards if we are to believe that.

If Safeway did business like that, they would fold in a week.

Hi Richard, this is exactly why there must be a stop brought to the assanine litigious fervor that ambulance chasing loafs like John Edwards bring against this country's honest businesses every day. Bushmaster's insurance paid that token of "shut-up idiot and go away" ransom, not Bushmaster. If left to Bushmaster, it would have gone to a very expensive trial and in the end, like every other case in history (except one communist judge in NY) it would have been dismissed. Does the Brady center tell you that? Look it up before you listen to any more of that dribble that an intelligent and worldy man such as your self has no business falling for. Which is again, why we must make the law read that *losers* in assanine cases like that pay *all* the legal bills. Either that or else ban lawsuits against gunmakers. You pursue these unconstitutional bans against guns and gun owners, well then we'll ban your lawsuits. Have it you way, you're going to make enemies of yourselves either way and the rest of us will go on with our lives. Even defending yours.

Gee what kind of idiots do you grow in Seattle? It's liberal-land for crying out loud, don't any of you folks obey the law? We take gun shop owners to

jail for less than that in the East, and ruin their lives for trying to make an honest living most of the time.

Hello Bob, whether I used a bow and arrow, a single shot musket, or an autoloader Remmington .308 rifle to take a deer is not the point. Self defense and American's right to keep and bear arms is not about hunting. Nowhere in the Constitution do any of the founding fathers who adamantly supported our permanent right to keep and bear arms, mention "hunting" or "sport".

Radio is regulated because the airwaves belong to the pubic. Use of a radio for survival (of life or property I will add) is not regulated in any way. Firearms are regulated because it is reasonable to restrict felons (ie: not peaceable citizenry) access to them, the same as we restrict the mentally or physically incapable or repeat offender drunks from driving an automobile on

our public roads. But use of a firearm for self-defense is not regulated by any Constitutional-supported law, although some states make saving your own life a near crime. In Britain it *is* a crime to defend your life *or* property with a firearm, and there are recent cases to prove that is the intent of the crown to make it so. Please don't pretend there is a legislature who upholds anything in Britain. If it were not for a very few brave men left there, the whole place would just fold to muslims and dutch pedophiles the way the rest of europe already has. To our brave friends in Britain, come to America, we await you with open "arms".

So Bob, whether an american owns a pistol, muskey, sport rifle, hunting rifle, assault rifle or sausage maker, it's none of your damn business anymore than your choice of radio manufacture or your ability to fix it or improve it is mine.

73,

Jack

Good Grief! No, that is *NOT* a Carolina Windom, which is an antenna
sold by Radio Works. Hopefully, they have it copyrighted and therefore
can object to the above BS. See it at

http://www.radioworks.com/ccwcover.html

The antenna you mention is simply an off-center-fed dipole, not really
a Windom at all. (Why are people with 65 IQ's allowed to build web pages?)

the 65 IQ has nothing to do with it. The problem is that the manufacturer
sold it as a Windom...
and it is as it is off center fed... with a simple balun and coax, but the
opposite is not true.
Ok it is not a carolina, it 's only me who mixed both designs.

You are shooting your own argument in the foot. The people you are describing are *LAW-BREAKERS*, not law-abiders. There are already laws against what they are doing. They already broke the law and you want yet another law for them to break??? Why not advocate enforcing the existing laws which are not being properly enforced? How many laws do they have to break before you realize that law-breakers don't obey laws? As I said before, you might as well be advocating laws prohibiting hurricanes from hitting Florida.

Gun control laws don't keep guns out of the hands of criminals.
Gun control laws keep guns out of the hands of law-abiding people who need guns to defend themselves against criminals. You and the criminals would like to see all law-abiding citizens disarmed and helpless.

In case you missed it: LAW-BREAKERS don't obey laws. They don't obey the present laws and they won't obey any new laws that you are advocating.
To keep the thread on topic: IMO, you can't see the forest for the trees.

If at a low frequency , put a resistor across the high impedance of the balun equal to the design impedance and check the swr. Frequency does not really have anything to do with it, just it is sometimes hard to get a resistor that is not reactive and is acting like a resistor at the higher frequencies.

Build 2 of the baluns and connect them back to back and put a 50 ohm dummy load on the second one, assuming you are going from 50 ohms to the 450 or 500 ohm impedance unbalanced. Then measuer the swr.

Couple ways-- Requires non inductive resistor -- If have a
MFJ-259 (ect) or a Noise bridge, connect your resistor to the X9
output side of the balun, connect the input side of the balun
to the MFJ, and sweep the frequencies, -- the meter should
stay FLAT, at 1:1 (or close to it) over the range it is designed for.
or, the noise bridge noise level should remain unchanged (same consider
ation). or, (this requires a POWER, NON-inductive resistor),
with a SWR bridge, XMIT into it (again on various freqs)!!
SWR should be flat over the range you want to use! Jim NN7K

That's simple. Because the criminals are armed with battlefield
weapons. Don't know about you, but I think it's stupid to take
my 66 year-old fists to a gunfight.

> How many times do you need to shoot that beautiful deer before you
> drag it to the sausage maker?

Deer don't shoot back. Criminals, including terrorists do, and
sometimes with fully automatic weapons. The criminals obviously
want the ordinary citizens to be disarmed. But why should you
want exactly the same thing as the criminals?

Did you know that the crime rate is falling in the concealed-carry
states? Did you know that a majority of states are concealed-carry
states? If you were a criminal, would you really want to take on
someone who might be packin' a concealed Colt .45?

3424. Volts at the ends of antenna wires.

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-20 00:19:53 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>

> as low as 100 watts. Be careful!
>
==========
Hi Bill,

A half-wave dipole is a resonant tuned circuit.

A 40 meter dipole using 14-gauge wire has a Q of about 11.

At 100 watts there is 85 volts at the feedpoint.

The voltage between the ends of the antenna is 85 times Q which equals 956 volts.

Therefore, the voltage between one end of the antenna and ground is only 478 volts.

And this falls to a much lower value when the end of the wire is in contact with anything by virtue of the very high antenna impedance of around 1500 ohms.

Furthermore, the antenna is immediately detuned when it comes into contact with anything and Tx power falls.

From where do you get your "thousands of volts" - the old wive's monthly magazines?

There are far more Californian forest fires caused by arsonists than 100 watt transmitters. Fortunately, it doesn't seem to have a bad effect on the quality of the wine.

I will deal with only one of the misconceptions.

Actual assault weapons have been tightly regulated (in many States, civilians can not legally own them at all) by the Nation Firearms Act (NFA) for the past about 70 years. Very, very few crimes have been committed with such weapons.

The law that just expired contained a definition that was equivalent to defining the number pi as 3. It defined rifles with certain cosmetic features as being what they could not be - "assault weapons." The law used emotive words to make it appear that common rifles were the same as what had been dealt with by the very old NFA. Even the media showed police owned machine guns (regulated by the NFA) firing and then left the impression that those were the rifles covered by the just expired law.

In short: the law that just expired was a fraud - assault weapons continue, as they have for 70 or so years, to be very tightly regulated.

Gun control is using both hands.

In any event, if the trees are at all flammable, best use some
non conducting rope (that won't absorb moisture when it rains)
to support the ends of the antenna away from the tree limbs.
The antenna would work better without those lossy tree trunks
right next to the ends anyway.

Reg Edwards wrote:
> From where do you get your "thousands of volts" - the old wive's monthly
> magazines?

Try this, Reg. A dipole is a standing-wave antenna. Most people know
that the voltage 1/4WL away from a current maximum is pretty high.
Since the current is zero at the end of the dipole, all the energy
is contained in the E-field. So what is the voltage when all the
energy is in the E-field?

A 1/2WL dipole is a lot like a lossy piece of 600 ohm transmission
line. 600 ohms is in the ballpark of the natural Z0 of a dipole if
there were no reflections on it, i.e. if it were terminated such
that reflections were eliminated thus turning it into a traveling-
wave antenna.

If one assumes that at the dipole feedpoint, (VF+VR)/(IF+IR) = 50 ohms,
and if the traveling-wave impedance of a dipole is 600 ohms, one can
calculate the ratio of VR to VF. Turns out to be about 0.9. So VF is
about ten times the feedpoint voltage. At the open-circuit at the end
of a dipole, VF adds in phase with VR so the voltage at the open-circuit
end of the dipole is about 20 times the feedpoint voltage.

The feedpoint voltage at 100W is about 70.7V. Therefore, the voltage
at the ends of the dipole is about 1414V RMS. Multiply by 2.8 to get
peak to peak at about 4kv.

When I worked for Schlumberger in the oil fields, we could easily
draw a 4 inch arc if someone got their aluminum hard hat too close
to the mobile radio whip during transmit. How much voltage does it
take to draw a 4 inch arc?

I wonder if those same states might also have the highest number of
crimes of passion committed with firearms? Don't know, just asking.

> If you were a criminal, would you really want to take on
>someone who might be packin' a concealed Colt .45?

Personally, I wouldn't attack someone packing a cap pistol. But if
your argument is carried to its conclusion, that law abiding citizens
should have guns as big as what the worst criminals carry, then we'd
all be walking around with machine guns. That's fine, until somebody
loses his/her temper.

One of the staples of San Antonio TV news is showing some family on
the South Side mourning the death of yet another kid killed in a
drive-by or whatever -- happens about two or three times a month.

Seems to me there is a big difference between people losing their tempers, and drive by shootings by gang members, such as the fact that normal citizens don't lose their tempers and shoot strangers. If you think they do, show me some evidence.

Hi Richard:

I don't want to attract any more spam. But am trying an experiment with MailWasher. My ISP (Telus) has a very effective spam filter, and very little gets through, but I turned it off as I wanted to see if bouncing spam would stop it. I have been going now for three months and do not see much change. Averaging about 33 spam messages a day. I plan to run the experiment till the end of the year or so.

What bothers me is how much of this junk eats bandwidth up, and would like to find a way to eliminate it. I have known many people who end up getting so much spam that they dump their address and get a new one. I was wondering if these spammers continue to send spam for ever to non-existent addresses.

Had an e-mail from a local ham who says he was very successful with MailWasher, so will give him a call and see if I am doing something wrong.

That should work fine.

> Build 2 of the baluns and connect them back to back and put a 50 ohm dummy
> load on the second one, assuming you are going from 50 ohms to the 450 or
> 500 ohm impedance unbalanced. Then measuer the swr.

That won't work. Let's say the balun is supposed to be 9 to 1 but is
actually 25 to 1, and the second balun, likewise supposed to be 9 to 1,
is also 25 to 1. The balun on the output side will transform 50 ohms not
to 450 ohms but to 1250 ohms. Then the one on the input side will
transform that 1250 ohms back down to 50 ohms.

Hi Frank,

Simple: Encrypted email with public keys, or private keys to verify
sender/recipient. The technology has been available for years (PGP),
and the RSA algorithms are public domain now (and have been for a
couple of years). It would kill the industry overnight just like the
"don't call" list instituted last year. The problem is inertia, and
Micro$oft wanting to do it their way (as if they had a clue about
network security).

Mark wrote:
"Is this practical?"

Trees near an antenna cause some loss. It`s hard to quantify in advance, but in ww-2, the signal corps estimated that hf loss is usually negligible if horizontal polarization is used (page 241 of 'electrical communications engineering').

I`ve found that horizontal HF dipoles, directly fed by coax in various Bolivian Chaco Jungle sites, below the the tree canopy, but not too close to the trees, communicated well with Cochabamba and La Paz, Bolivia. So, the dipoles didn`t suffer too much from the trees. The Signal Corps was right.

Hi Richard,

>Build one: 4 resistors, Zener diode, battery.

That is the easy part, the not so easy is that AFAIK you need a
(mediumly good) transformer to get the signal from the noise
bridge to a receiver without altering the bridge.

I had thought about building a simple bridge, but ferrite cores
are close to impossible to get in Barcelona (Spain). You get them
but with no info at all, just size and color. If you ask anything
else the shop person will look at you as a trouble-maker.

Appart from that, I have finally found the schematics of my
receiver. Some low-pas and diode limiter and strait to the gate
of a fet. This explains the "not exactly 50 ohms" thing.

Hi Richard, it's not easy to compare your rainforest canopy to loblolly pines, but at approximately 50' my dipole is well below the pine canopy, and well surrounded by them. If there is an impact from the pine trees it would be hard to quantify since the dipole exceeds everyone's expectations for short and long range performance. We have heard comments that pine-fron clusters when wet, affect a near field, but that has not been our experience. Neither does snow, ice or winds. Overall, there appears to be no effect on the antenna being in fairly close proximity to many tall trees, and suspended from them.

Best regards,

Jack

That was the Signal Corps conclusion for horizontal polarization at HF. For vertical polarization, surrounding trees are better energy absorbers. At VHF and UHF, absorption gets worse and worse as frequency goes up. Too much foliage is impenetrable at VHF and UHF, regardless of polarization, humidity, ice, snow and wind.

The Signal Corps advises trying horizontal HF antennas among the trees to avoid detection by the enemy.

No.... I just know how to spell and pronounce words correctly (it's a
gift, I tell you!). 'Pronunciation' is one of the most frequently
mispronounced words.

At least our public schools are a bit classier than the American public
schools (because they don't let the public in). However, I doubt if many
of their inmates pronounce 'pronunciation' correctly.
Ian.

Toni wrote:
"This explains the "not exactly 50 ohms" thing."

The FET input resistance is high and a shunt diode probably has high impedance at low signals.

The antenna appears as a generator at its resonant frequency with an internal resistance equal to its radiation resistance. As frequency lowers, so does radiation resistance. The antenna`s series capacitive reactance rises rapidly too. Due to lower antenna loading, a high receiver input impedance does better with a too-short antenna than does a 50-ohm input. But high-impedance input may be more susceptible to interference and overload.

Maximum power transfer to a receiver occurs when there is a conjugate match between the antenna and its receiver. This may, however, not give the best noise performance.

Best regards, Richard Harrison, KB5WZI

Hi Dale,

I think David's point was that you can prove symmetry through the back
to back test, but you don't "know" what it is symmetrical about. Was
that 9:1's we were testing, or the 25:1's?

I can imagine a 25:1 transformer, but I sure haven't seen the
configuration for a 25:1 BalUn - that has to be one nasty mess of
connections staged across several compound BalUns.

This is a good, first-order test. But, as warned, different pvc manu's give different results. It wasn't made for s-band RF. You must test it thoroughly without extrapolating. Some is almost OK; others are really poor. Sure ain't kidex.

Hi Toni,

Not necessary, but not impossible either. We will proceed as if you
do need one.

>I had thought about building a simple bridge, but ferrite cores
>are close to impossible to get in Barcelona (Spain). You get them
>but with no info at all, just size and color.

Then those have a high chance of being Powdered Iron core. Wrong
cores.

Find a swap meet where old computers are being offered, especially old
cables. Look for those power or video connectors that have a plastic
cylinder at one end, 1 or 2 cm near the actual connector. Cut away
the plastic, cut away the wires: you have a high chance that you are
holding a ferrite core that will work.

>Appart from that, I have finally found the schematics of my
>receiver. Some low-pas and diode limiter and strait to the gate
>of a fet. This explains the "not exactly 50 ohms" thing.

This addition suffers from the misapplication of a comma as a
substitute for the pause in speech - that, or it is entirely out of
place. Either way its addition is in error. The redundant period at
the end is also in error. The comma after the ITYM is awkward at
best.

Hi OM,

The "however" is set off from the rest of the sentence because it is a
transitional adverb. Contemporary usage would allow it to stand or
not be used since the sentence is short. By adding the second comma,
you render " I doubt if many of their inmates pronounce" as a
non-restrictive clause. This means that its absence would not alter
the sense of the sentence. This is obviously not the case above.

Oh, honestly. Real antennas have been used at optical frequencies for a
decade. There's a current DARPA BAA on just this topic--for uncooled
infrared imagers. My day job involves trying to use this effect for optical
interconnection in servers and routers.

Cheers,

Phil Hobbs

It is not a pause in speech. It is correct grammar.

Also, the comma after, "ITYM" is equally as correct grammar.
Both introduce the quoted text.

The full stop, not a, "period" for English-speakers, at the end
of the sentence is not redundant. It marked the end of my sentence.

When I've used a low-pass filter, I've simply attached it to the
output of the transceiver with a double male coax connector, so the
unwanted higher harmonics go directly into the filter, and then the
hopefully clean signal moves on to the antenna feedline.

I think you would be better off with a different antenna all together. A 1/4
wl antenna with the full length mounted vertically would probably be better
than this 1/2 wl antenna. Or center feed the horizontal section and and let
the ends hang down 13ft. An inverted V may fit in your 40 ft of space.I am
assuming you have a space problem.

Source record: 89299

I guess you could say that once they saturate magnetically more power
from that point on will be a loss <grin>

Resistive wire losses as well. ie the balun gets hot (Altho saturation
also leads to temperature rise)

I am not that knowledible of baluns but note that the number of turns is
a compromise of sorts. The Xl is suppose to be some multiple of the Zo
and Zi (10x I think is a good number) Too high a number of turns and it
saturates at a lower power, too low and resistive losses become a factor..

I am prepared to be shot down on this.. I learn as I need to!. ie When I
need a balun I'll read up on them...!

My guess is that the input impedance of this antena is on the order of a few
hundred ohms as compared to the input impedance of a normal J poles
"radiating section" which would be a few thousand. A balun may be the better
way to go.

Jack, if you go here while these stories are up http://www.woai.com/
see for yourself: a domestic argument that ends up with one guy dead,
one lady with a bullet in her neck.

Another guy shot, playing basketball. Another shot in an alley.

Typical Sunday in this town.

I ain't "trotting out lies." Just observing life.

Have fun.

I found out
that he's also living with a felon who has lost her CPA license due
to tax fraud. (details below) Man, this N8WWM guy has real issues!

KC8QJP Lee Kathleen <---- her address is the same as N8WWM on QRZ.com

http://acc.ohio.gov/dhearing.html
http://acc.ohio.gov/bdmn0401.html
FORMAL DISCIPLINARY HEARING-KATHLEEN R. LEE
Chairman Woods noted that Kathleen Lee was issued CPA certificate 36,525
on July 15, 1998. The hearing was to consider disciplinary action
against Ms. Lee's CPA certificate pursuant to Ohio Revised Code section
4701.16(A)(5), conviction of a felony under the laws of any state or of
the United States. Ms. Lee was convicted in the United States District
Court, Northern District of Ohio of five counts of Aiding & Assisting in
Filing False Tax Returns, a violation of 26 USC 7206(2), on June 12,
2000. Ms. Lee did not appear at the hearing. The Board agreed to
deliberate the disciplinary action in a later executive session.
Action taken.
Kathleen R. Lee, CPA 4701.16(A)(5)-Convicted of aiding & assisting in
filing of false tax returns. CPA certificate revoked.

Ok. I'd love to see details on it. I find it hard to believe, since I've never seen an area of the country with a murder rate like that. Got any newspaper links where I can read about them?

I will have to make one exception on my previous staement - about 6 days ago a guy stabbed to death 3 people here in Minneapolis. I have, with tongue not too firmly in cheek, suggested we need to investigate knife control legislation.

TIA

I believe that insect eyes have little connection to the recent news about carbon nanotubes being arranged into 'antennas for light'. I think that the differences are quite clear.

The news is not BIG NEWS - quite the opposite... ;-)

> ...in Truro?

Truro? Puhleeze....couldn't stand it. Way too much traffic congestion for such a small town.

I know it's natural to poo-poo all things new, but this NG takes the cake sometimes.

CNN, "Until now, no one had been able to make a device small enough to act as an antenna for [visible] light." ['visible' light is from the CNN article's lead paragraph]. Seems pretty clear that the news is the size. Other than scale, they've simply made some good ole' fashioned vertical monopoles.

That DARPA link (above) leads to 'blah, blah, blah' about millimetre wave and IR - not visible light. And they're looking for someone to invent same - it wasn't exactly a purchase order for an off-the-shelf product. And (apparently worth repeating) it wasn't for visible light scale.

If anyone can provide any 'old' news for actual 'EM' antennas for ~visible~ light, please post the link and be sure to alert Boston College(*) and CNN and DARPA. Insect eyes don't count (not even close) - not EM technology.

(* OMG - Let's quickly put any obvious fractal derivatives into the public domain here and now.)

> SWR should be flat over the range you want to use! Jim NN7K

That's the way I have checked impedence transformers in the past.
I have found that a Variable resistor works pretty good for testing with a
MFJ-259.
Used it for half-wave coax baluns, as well as wind-it-yourself transformers.
Set the variable resistor to the expected value to match, then check it with
the MFJ-259,
it worked for me - on hf and 2-meters. Didn't try it on the uhf freqs.
I used to like to use 300-ohm twinlead because the weight didn't make the
dipole sag as much as coax.

Outgoing mail is certified Virus Free.

O.k. Bob, I'll be kind and say you are not trotting out lies, you're just delusional, because you imagine these are normal people, when every once of common sense you have tells you otherwise. And the news stories offer no details whatsoever, except the area of town (Lincolnshire on the east side). Suppose you mosey on over to that basketball court and tell us who plays there. If they ask you, tell them you're making sure they are just normal, reasonable law-abiding people, the kind that get mad and shoot both friends and strangers
over trifle matters because they had a gun. Drive bys are always gang related Bob, if you're not quick enough to understand that call your local police and ask about it. None of your stories (2 in all, not 5) are nornal law abiding citizens. Curb your enthusiams for sensational Dan Rather reporting and stick to facts next time so we have something to talk about, o.k.?

By the way, see your own link and read about the "Home Invasion Suspect Charged with Murder" in your nice neigborhood of ordinary law abiding folks.. Another homeowner dead, murdered in a home invasion while her elderly parents watched her shot to death, helpless to stop the 23 year old bastard kill her in front of them. Had they been armed, there would be a dead felon, not a dead daughter. Wish it was your daughter Bob? Want to watch her savagely beaten and shot to death in front of you? Plead with an insane killer for her life and then for yours? You bet you do Bob, you sorry wipe. You're happy that poor woman is dead and would sacrifice your own daughter too, rather than own a nasty gun and learn how to use it. No? Tell us where you differ on these fine points here Bob.

Have a nice evening.

Jack

3493. Any experiences with inverted L and elevated radials

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-21 01:57:51 UTC
From: k9sqg@aol.com
Message-ID: <20040920215751.08200.00000872@mb-m06.aol.com>
Source record: 89314

Just wonder if anybody out there has experimented and compared inverted L performance with elevated vs buried radials, particularly on 160 meters.

If I would also like to listen to satellites flying over head which antenna would be better?

http://tinyurl.com/593dm

or this one?

http://tinyurl.com/4k794

I like the 2nd one(discone) slightly better since it will likely fit in my attic better and I can also use it as a TX antenna later on. I have heard they perform poorly though.

Matt

> Looking for a broadband scanner antenna for my attic. Would like 29-900Mhz
> receive and TX on 150 & 450Mhz ranges. TX is not that important really.

I am looking for a Spectrum antenna, specifically to pick up CB frequencies. I believe this is the Motorola brand of antennas. I have seen these before, but all the local Motorola dealers say they don't know about them. Any ideas?

Thanks

Are you referring to a mobile or fixed (base) antenna?

Motorola often purchased antennas from other OEM mfg. to their
specifications (e.g. Larsen or A/S for mobile antennas or dB for fixed VHF
antennas)

Hi OM,

Well, you said as much before without really saying anything. Beliefs
are simple to express, "what is different" is what I asked for. The
similarities outweigh the perceived differences.

More than two cars at an intersection is a traffic jam? If scale is
anything, this may be more your problem with antennas for light and mm
wave models at IR.

You would need to get them fairly high off the ground to really do
well.
160 is no different from any other band as far as ground losses vs
height above ground. The height in wavelength and number of radials
for a certain degree of efficiency is pretty well cut and dry. In
order to use a fairly low number of elevated radials and have high
efficiency, you must have the antenna at least about a 1/4 wave high.
At a 1/4 wave up, about 10 or so radials will equal 120 on the ground.
But a 1/4 wave on 160m is 130 ft...:(
You only need about 3-4 radials at 1/2 wave up to do the same thing...
At around 1/8 wave up, you would need appx 60 radials to equal 120 on
the ground. And thats still 65 ft high at the base of the antenna...So
I'd scratch the elevated radials unless you have a tall tower to
support the vertical.
Unless you want a load of wires hiding the view of the sky, you would
be better off planting them on the ground. If you try using a low
number of them, and real low to the ground, like say 5-10 ft, the
efficiency will be pretty low. Almost as bad as no radials..:(MK

Yes, but my main objective for all this is feeding the receiver
with the signal comming from the antenna well above the roof, and
(try to) avoid feeding the noise picked by the feedline on it's
way down. Light dimmers, fluorescent tubes, the computer, TV,
etc. I can notice a noise difference when turning them on/off,
and that's what I want to solve/improve.

From: Ken <cprstn54zz@att.net>
Message-ID: <fab0l0h27s0fgg7940npokg5m7r6duv9cu@4ax.com>
Source record: 89227

What options do I have in bringing a longwire antenna and tuned
counterpoise ground to my tuner -- in addition to using the terminals
provided?

Unfortunately, the tuner is 15 ft from the window that both leads will
be coming in from. Rather then string the wires (both RF hot) across
the room, can I connect them to a balun and run co-ax? What balun?
Will I experience large losses in the coax?

Any point in hooking the two leads to ladderline and running that? If
that works, do I still use the ground and longwire terminals of my
tuner? Or the balanced antenna terminals?

If the ladderline works, how long can I make it? It would be more
convenient to have the longwire run to the trees from my attic (and
the counterpoise leave from there), rather than my shack. Could I go
to 50 ft of ladderline?

Your question cannot be answered unless you specify the maximum allowable temperature of the wire and whether your antenna is in northern Alaska in midwinter at midnight, or in New Mexico at midsummer at noon.

But to be on the safe side, allow for a dissipation of 1 watt per foot length of dipole wire which will then get warm in the centre, somewhat above ambient, when in a slight breeze.

So for a 130 foot, 160-meter dipole, allow 130 watts dissipation. This antenna will easily handle 1 kilowatt of Tx power at a typical efficiency of about 87 percent for copper-plated, stranded steel wire.

But the current distribution isn't linear, and the loss is I^2R, so I would think you'd have to know the max current, and work it that way.

OK. Coax is almost impenetrable at HF. But a directly connected antenna can accept signal from the coax ecterior unless a balun is used at the antenna end of the coax.

I recall using a General Electric "V-Doublet" receiving antenna kit in 1938 that used twisted pair for the transmission line. Broadband transformers were used at each end of the transmission line. They were interchangeable. The high impedance of the antenna and receiver were matched to about 100-ohms, the approximate impedance of the twisted pair.

It worked well on all bands for the multiband GE receiver. The "V-Doublet" antenna system ignored interference to its transmission line.

Coax could be used to replace the twisted pair as the primary and secondary of the transformers are separate and isolated.

Best regards, Richard Harrison, KB5WZI

>etc. I can notice a noise difference when turning them on/off,
>and that's what I want to solve/improve.

Hi Toni,

Often, this problem arrives through the AC connection of your radio,
and not over-the-air. You can test this by removing the power cord,
and running off of batteries.

If your set runs off of AC only (no battery option), try borrowing a
portable radio that covers the same bands and use the same
antenna/ground.

If this last step reduces the noise (with the noise sources ON); or
you cannot obtain a portable radio, then try one more option. Use an
extension cord (so that you don't have to move the radio, or
disconnect and move antenna leads) and plug your radio into a wall
outlet in another room. Move this plug around to see if it impacts
the noise problem.

If you find noise is variable by this technique, you are sharing a
circuit with noisy sources and the noise is coming in through the AC
supply. How you solve this is a function of what choices are
available to you. It may mean moving your listening position, or
buying/building an AC line filter (which should not be
expensive/difficult for a low wattage item). This also presumes that
the AC distribution system has a good ground (not always available).
If this is not available, you may need to do it your self, but this
needs to be investigated with care.

> 250 pound guy in the process of raping your daughter?

Umm, Cecil. I support private ownership of guns, and as few laws that regulate such ownership as possible.

But your argument is specious. That 250 pound man may just use his own gun, make you redundant, than continue to use the gun to make sure your daughter stays compliant.

There is plenty enough emotion to go around on both sides, and your argument is just one more.

And since you want that answer, I would use my rifle *if* possible, however, I would have to realize that if I do use it, I would face the possibility of seriously wounding or even killing my daughter. If such an act is taking place, the two would be in obvious close proximity, and bullets do not always travel a straight line. The bullet might very well pass through him, and enter her.

Probably the best course of action is to (unfortunately) wait until he is temporarily incapacitated as will happen, at that point he will likely roll off, and then wait for your moment....

Knowing that you are a wine aficionado, I would mention that there is serious concern about the future quality of the wine. It appears that global warming (which doesn't exist ha ha) has been on average warming the regions of California where the wine grapes are grown. This is causing them to ripen prematurely - at least as far as making the best wine is concerned. Let us hope that a solution is in the works!

I noted that i support private ownership of guns before.

But your argument is a bit too simple.

Case in point:

A young boy shot his sister with one of the family guns. It turned out that the father was a real gun person, and firearms were all around the house. In fact, the children's toy guns were stacked along with several real weapons. The little fellow just picked up what he thought was another toy and pointed at his sister. Took her head off f I'm not mistaken.

The parents were tried on reckless endangerment of children. They fought the case as a gun control issue.

Another case is closer to home, much closer. Some years ago, there was a neighbor up the road from us that was shall we say - unusual. Prone to disturbances. He also let guns lay around the house. One day his son brought one of the guns (loaded of course, in case someone breaks in and tries to rape his daughter) points it at my kid, and thank God didn't pull the trigger.

The police confiscated his guns, and he went on a tear about having his rights violated.

Point is, all the "guns don't kill people, people kill people", and who's raping who's daughter, and all the other emotional arguments wouldn't have meant much to me would it?

The problem with too many people regarding gun laws is that they only think of the back end of things. It's all after it's over.

> In case you missed it: LAW-BREAKERS don't obey laws. They don't obey
> the present laws and they won't obey any new laws that you are advocating.

> To keep the thread on topic: IMO, you can't see the forest for the trees.

On both sides of the issue

Hi All,

The Wine out of the Pacific Northwest is fast gaining a high
reputation. Could be from that same warming trend.

I must add that this last summer was one of the muggiest I've lived
through here. Humidity in the 80s. It almost competes with D.C.'s
June weather when I was back there during Reagan's funeral.

There's a Wasington State Merlot (I'll remember the name next time I look at
a wine list) that I like all too much.
Now how are we going to connect this to antennas? I know! Empty wine bottles
make great base insulators for verticals!

My longwire could almost reach the Chateau Ste. Michelle winery (but
was closer to the Columbia winery and closer yet to the Red Hook ale
brewery).

==========
Yes Dave, I know. But I did say the wire gets warm at the centre. Sorry I forgot to say it remains cold at the ends except for the small conduction of heat along the wire. And it does not get quite so warm when it rains or snows.

Actually, the current distribution along a 1/2-wave dipole is exactly a sinewaveform. This is arithmetically very convenient because the linearly distributed wire resistance then behaves as though it is lumped at the dipole centre with a value exactly half of the overall distributed value.

Now the end-to-end resistance of a 1/2-wave, 160-meter dipole, made with 26-gauge copper-plated wire, is about 22 ohms. Therefore the feedpoint resistance of the antenna is the radiation resistance of 73 plus 22/2 ohms = 84 ohms.

Therefore, with Tx power equal to 1000 watts and a current at the centre equal to 3.45 amps, the overall loss of power dissipated in the antenna wire is equal to 3.45 squared times half of the end-to-end conductor resistance of 11 ohms. Which (as I said in my previous message) equals 131 watts.

Which raises the wire temperature a harmless handfull of a few degrees Celsius. Actual temperature, of course, depends on the open-air ambient temperature at noon, in June, in the New Mexico desert.

Antenna radiating efficiency = 73/(73+11) = 84 percent, or a loss of 0.76 decibels, or 1/8th of an S-unit. Which, by no stretch of the imagination, is likely to influence the results of a contest.

Isn't it remarkable what a little bit of ohms-law and arithmetic can do?

Mathematics - don't make me laugh! <smiley>

Mathematics is what English infants school teachers refer to when whining for a pay rise. To such a level are what the western-world's standards of education have been reduced.

Reg
I went to public schools in Texas in the 50's and 60's.
There were no standards then. School was a pathetic joke.
If I hadn't had ham radio, cars and flying as teenage passions, I never
would have learned math or physics.

I don't think you should count on a perfect SWR match, either, and
should size for some amount of mismatch.

Worst case kind of thinking.

Ahh, I kind of enjoy Rush, or did until he started to get redundant.
But I wouldn't take him as a science adviser! ;^)

Seriously, I would be willing to entertain the notion that global
warming is not happening. But what I need is a good explanation of of
the mechanism keeping it from happening. Certainly the oceans can sink
some CO2, but only so much.

The effect of CO2 on thermal retention in the atmosphere is not bogus,
and there are plenty of other gases that are likely a worse problem,
such as methane. Methane is hardly being addressed now.

There are possible effects that will mitigate the heat retention, but I
want to know what they are, not just that the warming effec isn't real.
To say that global warming doesn't exist is not far from saying Ohms law
is wrong.

I wish proof, not politics. unlike El Rushbo, I don't think that every timee it snows is the disproof of it. We might check with our Canadian friends on how their growing season has been affected.

From: Floyd Sense <fsense***@risp.biz>
Message-ID: <ciq3cs$t3$1@news.chatlink.com>
Source record: 89248

Hi Evan. I haven't done a scientific comparison, but am currently using two resonant elevated radials with my inverted L on 160. They're only 8-10 feet off the ground. I'm sure the efficiency is rather low, but I've worked into JA land a couple of times with it and did quite well on 160 last season. The herd of deer living in the back woods, as well as the lay of the land make radials on the ground rather difficult for me. Based on my experience of last year, I'd say the two raised radials do better than the 8 radials I had on the ground in previous years. Of course, both situations are far from optimum on 160, but since I can work everything I can hear (no beverages), I'd say the antenna is adequate.

The fear of being on the wrong end of a 12 gauge prevents many burglaries.
I have seen interviews with convicts and also the book "More Guns Less
Crime" that bear this out.
It is my understanding that since the Aussies disarmed themselves they have
paid the price.
In Texas, CHL holders have a lower crime rate than the cops.
The last intruder in my house got a .357 magnum in the face; blew the back
of his head off.
He was a 5 foot timber rattlesnake. I had a model 19 Smith.

**** Post for FREE via your newsreader at post.usenet.com ****

I wrote:
> ...the differences are quite clear.

"Richard Clark":
> ..."what is different" is what I asked for.

My views of the differences were already explicitly listed:
>>> It's the difference between optics
>>> and EM (Yes, I know, I know...*),
>>> or between nerves and conductors,
>>> or between biology and physics.

[*I'm as in favour of the fundamental sameness of light to radio waves as anyone.]

I would have thought it an obvious and reasonable assumption that biological optical sensors, including insects, are typically based on 'wetware' (photochemical reactions). In other words, the question is - are the insect's optical receptors (INSIDE the photoreceptor cells which are themselves clustered INSIDE the purely-structural ommatidium) something functionally similar to a quarter-lamda conductors, or something related to an optical/photochemical sensor (wetware) ???

Here's a webpage that states that all eyes (including humans and the fruit fly, an insect) have the same genetic basis (read the whole thing carefully - it is interesting):
http://www.pbs.org/wgbh/evolution/library/04/4/text_pop/l_044_01.html

It seems that my assumption is not not only reasonable, but also seems to be correct. Eyes (human or insect) are wetware, not antennas. Just as I assumed.

Thus, K4WGE's comment (below) about the CNN news is not applicable.
"k4wge" supposed incorrectly:
> This antenna was invented much earlier, actually, as the
> compound eye of insects and other arthropods.

And to explicitly answer your question:
"Richard Clark"
> What's the difference in Truro?

Discussed in exhaustive detail above - couldn't possibly be more clear.

As you know, it is impossible to prove a negative, but here is as close as I can get:
www.google.com/search?q=%22insect+eye%22+monopole

'Your search - "insect eye" monopole - did not match any documents.'
[Can't use 'antenna' for obvious reasons - insects - think about it...]

The ball is firmly in your court to better my negative search results with a link that clearly supports the position that you appear to be supporting (insect eyes = antennas). I'm asking you to prove a positive. Can you point me to anything on the WWW that clearly backs-up your apparent (?) position that insect eyes are based on 'antennas'? I believe that your position, apparently supporting K4WGE's apparently incorrect statement, is nuked and a smoldering ruin, but I'm open to more data.

Also, if anyone has any links to prior art 'visible' light scale antennas, please post links. IR need not apply - could be ten times the size (maybe more).

> More than two cars at an intersection is a traffic jam?

It seems that you've never been to the Truro (that I'm referring to) on a Saturday. There are rumours that missing union leader Jimmy Hoffa might simply be stuck in traffic somewhere near downtown Truro, NS.

Hi Mike,

Check the folks who pay for crop failures: the insurance industry.

Won't be long before the red states (or is that states in the red?)
are clamoring for insurance reform, tax rebates, corporate welfare,
interest free loans, loan default amnesty, financial assistance...

Hey wait! That is where all the homeland defense funds are going
right now. New York City has been crying for help against terrorism
for 3 years now, and the funding has been shuffled off to high
terrorist profile sites like Paducah.

Well, if you ignore the ports, you can rest assured we won't have to
worry about exports. If we don't worry about exports there will be
more for all here (at depressed prices - think dust bowl). We won't
have to worry about the trade deficit either because if we ain't
sellin' we won't be buying (same port issue even if we did want a DVD
player).

I wonder how we're going to get the oil in? 15,000 mile sub-oceanic
pipelines with Iraqi suicide frogmen every 6 feet? I suppose we could
torch the beaches from all the spills and start a second "solar" power
industry. Global warming? I'll show you warming, stay away from the
surf!

Political denial covers a lot of uncomfortable ills.

There is NO sharp dividing line between rec.radio.amateur.antenna and politics. Or any other newsgroup.

It's just a matter of keeping topics in sensible proportion.

How else would I learn about Bush, puppy-dog Blair, atmospheric polution, the frequency of forest fires caused by 100-watt transmitters with short-whip mobile antennas high up in trees, and the impending state of the present excellent Californian winery's?

It's real enough; literally decimated the world's coral reefs.
But the atmospheric carbon budget is still not well understood.
However the weather, being a chaotic system, probably becomes more chaotic as more energy is added.
For an excellent discussion of chaos and the weather 1000 years ago see "The Great Maya Droughts" by my old buddy Dick Gill.
Glaciers and permafrost are melting. Ice core data suggest the CO2 in the atmosphere shot up with the industrial revolution and is at it's highest in 50,000 years.
I dove for NASA in 1970 at Tektite II in the Virgin Islands. I went back to the site at St John in 1997.
The coral was much harder to find. Where I remembered reefs was sand and sea grass.
I'm going back in January.
Over 10 years of diving in Hawaii I have watched the coral population at Tunnels Beach, specifically, diminish dramatically.
One of my grad students is from Puerto Rico. He's noticed the coral decline in his 20-odd years.
Just a couple of degrees dramatically moves the permafrost boundaries.
Any Alaskans here? Canuks?
How much are we at fault? Can we change anything? I think the answers are some or a lot, yes and no.

OB Ham topic. I operated W3YRQ's (Jerre I am sorry if I got your call wrong, it has been 34 years) KWM2 on 20 meter SSB from the Tektite II habitat.
I believe Jerre and I are still the only hams to operate on the ocean floor.

Hi OM,

There is a world of difference between nanotech conductors, especially carbon nanotubes, and conventional conductors. There is a world of similarity between nanotech conductors, and wetware as you describe it. In fact, one nanotechnology framework is the DNA molecule. 300 base pairs would be adequate for a quarterwave visible light structure.

Trying to force Newtonian physics into a Quantum solution fails not in the application, but in the explanation.

An 80M inverted V will work just fine on all bands using your 941D. There is nothing wrong with the rig. The difference between expensive 450 ladder line and the cheapest 300 twin lead will be insignificant. I ran my inverted V for 13 years using cheapo twin lead and never had a problem with dust, rain, or anything that the naysayers can come up with. If you use coax and a balun you will only be good for 80M.

Hope this helps...

Yes, I like the idea of verification, and have heard some people are using it. Anyway I will keep bouncing for the next 3 or four months to see if it diminishes my spam input. I know it is trivial to dump it when it comes in -- which I do -- but it just bugs me that it exists.

73,

Frank

In the States, it's getting hard to find 300-ohm twinlead anymore.
450-ohm line might be his only choice for a balanced transmission
line.

**** Post for FREE via your newsreader at post.usenet.com ****

Ref . News on CNN:
http://edition.cnn.com/2004/TECH/science/09/17/light.antenna.reut/index.html

PREFACE - history of this 'discussion'
"Richard Clark" appears to support K4WGE's
assertion:
>> This [CNN^] antenna was invented much earlier,
>> actually, as the compound eye of insects and
>> other arthropods. [And then he provided a link
>> to a crude drawing of an insect eye at nearly
>> macroscopic scale. <sigh>]

RC joined the poo-poo chant with "What's the difference in Truro?" His position isn't all that clear. He's maintained a small 'deniability' gap. Perhaps he will clearly state [YES/NO], without obfuscation, if he really does intend to support the above (incorrect) assertion.

My position is crystal clear. I think that there is some confusion between some nearly-macroscopic structural (non-optical) elements within an insect's eyes and the similarly shaped, but ~much~ smaller, carbon nanotube antennas. Insect eyes no more use 'antenna' elements than do human eyes.

We've also been sidetracked by the IR crowd - those that ignore the adjective 'visible' in the CNN article.

If anyone has any links to prior art 'visible' light scale antennas, then please post links. (That's about the third or fourth time for that plea...) As with George Jr, I don't think that even an offer of a $50,000 reward would help in the search.

back to our regular programming

"Richard Clark"
> There is a world of difference between nanotech conductors,
> especially carbon nanotubes, and conventional conductors.
> There is a world of similarity between nanotech conductors,
> and wetware as you describe it.

The above statements hardly constitutes a valid proof (even by the incredibly weak standards of the Internet) that insect eyes somehow represent 'prior art' for 'visible light antennas' (per CNN link at top) as asserted by K4WGE. Are you planning to provide any supporting links to support your apparent support of K4WGE's (incorrect) assertion ??? If you don't know, then when will you know?

"Richard Clark" continued:
> DNA... ...300 base pairs would be adequate for
> a quarterwave visible light structure.

I could quite reasonably ask, "So you really think that insect eyes use their DNA to directly sense light?" - but I won't. I will ask what point you're trying to support with that rather off-the-wall (*) comparison. (* off-the-wall because I don't believe that nature intends that DNA interact with visible light and I don't believe that it does. It's just silly and it doesn't support K4WGE's assertion in the slightest.)

"Richard Clarfucius" say:
> Trying to force Newtonian physics into a Quantum
> solution fails not in the application, but in the explanation.

Ah so Master (but it doesn't 'answer the mail').

Your post (as extracted above) fails to move your argument any further down the road.

I see the difference.
Perhaps it helps to explain that the carbon nanotubes are rather smaller
than the cells in the insect's eyes, and there's no lens involved.

On Tue, 21 Sep 2004 13:40:31 GMT, Ken <cprstn54zz@att.net> wrote:

>What options do I have in bringing a longwire antenna and tuned
>counterpoise ground to my tuner -- in addition to using the terminals
>provided?
>
Let me restate the question. The antenna is more properly a random
wire. The counterpoise is a multiband counterpoise made of rotor cable
with a separate [folded] resonant path on every ham band of interest
(here, 80 and 60/160)

Most sources say a random wire antenna is a dipole with one leg being
ground. Iam trying to apply this principle.

If my ground is instead a resonant [half wavelength] multi-band
counterpoise, Why can't this be treated like a balanced antenna? I
would like the random wire to leave my attic for a 225 ft [horizontal]
run through the trees and for the counterpoise to hang down along the
side of the house, leaving from the same spot in the attic. It seems
to me that connecting these two leads to ladderline should be the same
RF-wise as if I had a standard dipole there -- albeit with 50% less
efficiency.

The ladderline would run 50 ft to a tuner. I am not sure whether to
use the balanced antenna terminals (thereby involving a built-in 4:1
balun), or the random wire terminal and ground.

If I am missing something, I can't figure out what it is.

If I am onto something, Does the counterpoise have to resonant? Can
it, too, be a long [folded] wire? I understand that in some vehicular
apps, the counterpoise is made this way.

I am interested in knowing how RF hot the ladderline will be. It
would be best if it worked the same way it works with a standard
double zepp -- with each leg's RF cancelling out the other.

Source record: 89269

In my attic I have a dipole cut to the middle of the 40m band. I use a Ten Tec antenna tuner with it and I can tune it for 15, 20, 30, and 40m with some success.

The last 8 feet of wire on each end actuallly bends 90 degrees because my space wasn't long enough to lay the thing out in a straight line.

I have used this antenna and earned QRP WAS in 1999, 2000, 2002, and I need 8 more for 2004. My best DX was Reunion Island on 30m about 2 years ago, I was using a Ten Tec Scout at 4w of output.

I crammed this antenna up in the peak of my roof, and I'd guess it's maybe 28 feet off the ground, maybe a little less.

My advice would be to try it. You can always yank it down if it doesn't work for you. Avoid any metal you can up there.

Nope. I feed it with RG8X Coax.

At the feed point I do have it looped 6 or 7 times and taped together in an attempt to keep the RF off the shield.

I am amazed at how well this antenna works sometimes.

I have accumulated 47 DXCC entities on it in the last 4 years or so. It's no DX dream, that's for sure, but I can sit down anyday or night and have QSO's with it.

I run a K1 at 5w about 95% of the time, all CW.

I need to figur eout a way to stealth up a 80m antler sometime. Maybe next year.

I was unable to retreive any of the documents on the LOFAR website, so I can't comment on the details.

I do see that the Sky and Telescope article mentioned the work at Ohio State. This one is working at S band (3 GHz +/-) and is currently detecting TVRO satellites and the solar emissions. I'm not sure what type of antenna they are using, however.

I built the first prototype of the OSU system some 17 years ago, by the way, as my Master's thesis, so I think I am qualified to comment on this. The bandwidth of the LOFAR system is huge, percentage wise. There are a number of problems that have to be overcome to get this to work in addition to the RFI problem. I was able to ignore most of these problems in the prototype because I used a very narrow bandwidth (just a few kHz). Unfortunately, my thesis is not available on-line, but there is some information on this and the current desgin at www.bigear.org.

Are they perhaps using circular polarization? There is an advantage to this as most of the 'noise like' signals are randomly polarized.

As far as the VHF signal interference is concerned, it can be shown that most VHF signals arrive at elevation angles of 15 degrees or less, so perhaps they designed the antenna elements to have nulls at this angle.

Hi Ken,

Your question also contains the answer as noted above. This is a
formal definition in response which in an of itself does not negate a
practical outcome.

> leaving from the same spot in the attic. It seems
>to me that connecting these two leads to ladderline should be the same
>RF-wise as if I had a standard dipole there

Reasonable assumption, but there is nothing balanced about it that
confers the characteristics/benefits of being balanced. Balance is
with regard to two sides of a dipole, each in relation to ground. If
one of those two is intimately associated to ground (you qualify in
spades here), then the system is unbalanced throughout.

This gives rise to unbalanced currents AKA common mode. However,
common mode may pass unnoticed, and in such case it simply doesn't
matter. This balance is easily qualifiable visually: does each leg
offer symmetry to the other AND ground? Yours does not. There is
nothing fundamentally balanced about a long wire in the first place
irrespective of counterpoise treatments. This does not diminish any
perceived benefits of that counterpoise, but the counterpoise does not
confer balance as you describe it.

As to the matter of ladder line and its practicability. At this point
its choice is driven by the expectation where you anticipate large
mismatches and losses that attend them. Thus the ladder line answers
the problem of loss, otherwise it has no particular merit over other
methods. To respond directly to your statement above, yes you can
attach ladder line RF-wise as if you had a standard dipole.

I agree with Irv, I used 300 ohm tv line availabe at Radio Shack, Home Depot and Menards for 25 years, on an 80 meter dipole. I used several different tuners WITHOUT a Balun and fed the line directly. You can even put a couple of short leads on a PL259 and splice it to the Twin line if the only output your tuner has is an SO239.

For your next tuner, watch Ebay and buy a Johnson Matchbox for under $100. They will match most loads you are likely to encounter, and are designed for Balanced line.

I presently use some home made 450 line on a 60 meter (90 foot end to end) dipole, as that is what fits between my trees. I modified my Matchbox to make it load all bands with the 90 foot dipole, but you can get the same effect by changing feed line length if you have "problem bands".

Reg Edwards, program Dipole3 will let you calculate the difference in losses between the 300 and the 450 line using the actual hieght and length of your dipole.

3562. New program "Not a trap"

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-22 21:37:08 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cisra4gav1@hercules.btinternet.com>
Source record: 89133

Extract from program notes.

Program Name: NOTATRAP.exe Author: R.J.Edwards G4FGQ

A TWO-BAND ANTENNA WIRE LOADED WITH AN L & C PARALLEL-TUNED CIRCUIT

The LC parallel-tuned circuit is constructed exactly like an antenna trap. It
is located in the antenna wire and used as L or C loading at 2 other resonant
frequencies. Parallel-tuned circuits have a reactive impedance on either side
of resonance. On the low frequency side there is a +ve inductive reactance. On
the high frequency side there is a -ve capacitative reactance.

The purpose of the LC loading components is to detune the antenna wire from
its natural 1/4-wave resonant frequency. When the loading circuit is behaving
as an inductance the antenna resonant frequency is reduced. When the loading
circuit is behaving as a capacitor the antenna resonant frequency is increased.
The pair of resonant frequencies depend on the LC ratio, on wire length, and
on the location of the LC loading circuit along the wire.

For a given loading location along the wire and a given pair of resonant freq-
encies this program calculates the L and C loading-component values. The pair
of frequencies lie above and below the unloaded resonant frequency of the wire.
The LC circuit behaves as an ordinary trap at its own resonant frequency which,
by experiment, can sometimes be arranged to fall into a third amateur band. But
to calculate such a fortunate coincidence is beyond my elderly patience.

The program has a built in signal source which generates a wide-ranging
testing frequency which can be used to 'measure' the input impedance of the
antenna versus frequency, checking resonant frequencies and other antenna
characteristics.

Download program NOTATRAP from website below and run immediately.

yep, yep, what a comedy!

This guy is a jerk, has no clue about workings of antennas.
I tried to listen to this joker, but gave up after his statement that he managed (BS) to get the current accross the loaded radiator (against laws of physics) to be constant (with loading coils and helix inserted) and then he states (rightly) that efficiency of the antenna is proportional to the integrated current curve. Then the miracle: his shortened antenna of about 1/3 length over 1/4 wave vertical has the same effciency as (2/3 longer, rest of the curve) full size radiator. Shorter curve - same area? Clueless in ....
Looks like the cafeteria technician and physics department of URI are on the same wavelength as "Done" Rather. Giving amateurs and University bad name, setting themselves as a target for ridicule. I am glad I didn't send my kids to URI :-)

Good question- also print for sources, and loads and perhaps
all on the same page ?? Only work-around I have is
a program called " Screen Shot ", but that has its own set
of headaches-- Prints the WHOLE SCREEN- not just the dialog
on the screen you want to view !! Don't think these are just
text files for this program !! Would be a handy addition!

Hi Yuri,

Good question. We've always been able to input a wire list, but never
output one (except by transcription).

If it isn't too big, you can do a screen image capture and then print
the image.

Look in the EZNEC manual index under "Printing The Antenna Description". To see what the "Outputs" at the top of the topic means, click the Contents tab over the left window pane while you have the topic displayed in the right pane.

The three normally intelligent people posting on this thread weren't able to find this, and it's a question I'm frequently asked. Is there any way I can index it so people can find it more easily? What did you look under in the index before posting this question, and where did the two people responding look? Apparently people don't make the association between "antenna description" and "wires table".

Reg,
Can this be conscrewed as a combination loop/.dipole?
It would appear that you can place the L/C circuit at the center of the dipole and fed either with a delta match or a capacitive /inductive coupled dipole for impedance purposes. Could not quite fathom from your notes what it was exactly. I made a 160M rotatable dipole last winter based on the above and used the radio auto tuner control to change the values on the L/C circuit to move up and down the band because of the resulting narrow bandwidth at any set frequency or band.

With time, it is clear that the magnitude of the claimed novelty, versus the reality, is an unfortunate case of lack of information --this is my opinion-- based upon factual errors stated, and said, by Rob. He most certainly is not "a jerk". Seems like a sincere and dedicated fellow who has worked very hard on a very challenging problem. I regret that he has not made a sufficient case regarding novelty nor efficiency nor widebandedness: again--this is my opinion.

There is little that may be gleaned, moving forward, in the realm of antenna science: spurts in the past decade have, at least, milked the basic science dry. There is still fertile ground for application, a rich and satisfying endeavor upon which many here focus with rigour.

I'm looking for a good antenna analyzer. Resonant frequency,
impedance +/- and magnitude. It'd be nice if it would also feed the
results to the computer for display/plot. It would be nice to have a
plot of the antenna characteristics on screen.

I'm somewhat familiar with the MFJ unit, but wonder what else is out
there other than the very expensive commercial units.

Hi Roy,

So it would seem.

When I open the currents window, I can go to the File menu selection
and perform "save as."

When I open the source data window, I can go to the File menu
selection and perform "save as."

When I open the load data window, I can go to the File menu selection
and perform "save as."

When I open the far field data window, I can go to the File menu
selection and perform "save as."

When I open the near field data window, I can go to the File menu
selection and perform "save as."

When I open the wires data window, I can NOT go to the File menu
selection and perform "save as."

This is a lack of symmetrical design.

When I go to the File menu of EZNEC, I can select "Import Wires from
ASCII Table."

When I go to the File menu of EZNEC, I can NOT select "Export Wires to
ASCII Table."

This is a lack of symmetrical design.

When I am twice frustrated in trying to find an operation that would
flow from similar program controls, it is not intuitive to seek it
further in what is called a "description."

I like my data separable and even though I am competent to the matter
of building automatic parsers to obtain the data I am interested in,
this is just another pain.

There are a lot of units in the market a search at google wuld help.

Take a look at:

http://www.schomandl.com

For field aspects I would prefer the products of MFJ.

Regards,

Ralf

3579. 'Mini' Coax

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-23 09:57:50 UTC
From: woodtownuk@aol.com
Message-ID: <20040923055750.13199.00001001@mb-m28.aol.com>
Source record: 89150

I've got a roll of coax that calls itself 'RF 8 MINI' (plus a description in Italian) on the drum, and 'RG 8 SUPER XX' - but no manufacturer - on the sheath.

Other RG8X coax I've used has always had a foam dielectric, but this stuff is very stiff.

Anyone know who's it is and some idea of its spec?

3580. Making a simple antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-23 11:47:46 UTC
From: harshana@sumuthu.lk
Message-ID: <b2defa30.0409230347.5e754d0d@posting.google.com>
Source record: 89151

Hi all,

I want to make a simple antenna like the ones U see in cheap remote control toys. Can anyone give me a eqation that helps me to get the wire length when the freq. is given (I'm looking at freqs like 400MHz ~ 900MHz)?

Thanks in advance,
73,
Harshana

PS: I don't have amature radio license, but my brother - 4S7NR had. Unfortunately he had to leave us (he was shot in Iraq while working for ICRC in July 2003).

No, Chip.

I do not see any errors in your comments.

What I was saying was that building such a system as originally described is a daunting task. There are many problems to overcome, one of which is getting an antenna to work over a 25: 1 bandwidth with reasonably constant performance. Another is that the pattern of the array will change tremendously over the same bandwidth, but this can be "fixed" by using only part of the array at higher frequencies.

Maybe that is why it was "broke up"? Also keep in mind the reputation of news outlets as to technical accuracy.

My Maser's wasn't so much in antennas (although I did do a bunch of research to identify the problems and propose solutions), but more at the systems level to show how digital signal processing can be used to solve previously "impossible" problems. I recall that at the time the experts in Radio Astronomy thought the idea wouldn't work at all.

Yes. Actually not an element problem, but a problem with fixed height above ground; ground characertistics; mutual coupling; and element spacing--I am sure you know this; others might not.

They were wrong; you and Bernard Steinberg (at Valley Forge/UPenn) showed otherwise:-) BTW, I read your thesis about 10 years ago.Nice work. Others might also like to know that a synopsis isup on the NAAPO site.

I think the Euro folks are too jazzed by the computational technology end and have lost sight of the overall goal. That is my personal opinion.

Aunwin, it would be impolite of me not to reply to your direct question. But for ages, on and off, I have tried at regretably increasing intervals, entirely unsuccessfully, to understand what your combination loop/dipole is all about.

So although YOU may somehow manage to construe some sort of relationship between a loop/dipole, whatever it is, and a lumped LC circuit inserted in a random length antenna wire, I'm afraid I'm in great difficulty.

In view of the amount of work involved, and the likelihood of it being fruitless, I propose for the time being to leave the matter in my pending tray and pour myself a glass of Bordeaux Claret. If unfamiliar with the beautiful deep red liquid you may like to try a glass yourself. It does help.

I'm very sorry that at present I'm unable to be of more assistance in your quest for recognition.

Yours, Reg, G4FGQ.

A Lot Of Crazy Folks wrote:
"Perhaps you could also take a moment to confirm that you understand the difference between an antenna and a solar cell."

Reciprocity rules antenna action. I`m not sure electricity through a solar cell will cause it to emit light.

Electricity does not travel through a void. Fields travel through voids.

A radio antenna is a transducer that converts between r-f fields and r-f electricity.

A solar cell is a transducer that converts between light fields and d-c electricity.

Radio waves and light waves are EM fields that differ in frequency.

Reg,
You emphasise that "it is not a trap", a trap being a loop circuit that provides a desired low impedance path and a blocking high impedance for another band. You go on to say that the circuit you refer to allows all of the antenna to be used for both bands! Thus the L/C loop must provide a low impedance path on BOTH bands according to your statement which is certainly different to a "trap".
From your statements I thus see your L/C cuircuit as a "loop" which can be placed at an apropriate point in a radiating element.
Les Moxon refers to a similar antenna in his book where the loop is placed in the center of a dipole and which he calls a resonator having a capacitor and inherrent inductance.
It was Moxons antenna ,which is what I refer to as a combination loop /dipole antenna, that illustrates the use of an L/C circuit in antennas and what I used as a basis for my 160M antenna which worked quite well. Thus it was your own comments that instigated the original question.
Hopefully when you read this your mind will not be in a befuddled state created by claret and before you waddle of to the local pub so that you can respond without sarcasm
Best Regards
Art

Some more "Trivia" for you and other interested parties....

The actual idea was conceived by Dr. Robert S. Dixon W8ERD, who at the time was Assitant Director of the Ohio State RadioObservatory (Big Ear) and Director of the Academic Computer Center. I was working there as a Graduate Research Assistant (official title) and Chief Engineer (unofficial title) and had not yet decided on a thesis topic. He was wondering if it would be possible to digitize the signals at each antenna element in an array and then, through digital signal processing, form all possible beams in all directions simultaneously. And the rest is history, as the saying goes.

Also, I had previously read the book Imperial Earth by Arthur C. Clark, where he describes a space based array that could look in all directions simultaneously. He called it "Argus", and I thought that we should use the same name for our system. My prototype, however, was called a Radio Camera since the basic idea was to form a picture of the RF environment, and the name Argus is now being used for the present system at OSU (not to be confused with the system that uses satellite TV dishes at many locations).

You'll get a laugh out of this... My original system used a PDP-11/40 with a whopping 10 MB of hard disk. I had the whole thing to myself as exclusive user. Even at that it was too slow (even with a 10 kHz signal bandwidth), so I collected the raw data and processed it off-line. I used weather radio stations at 162.55 MHz as my sources since they all run the same power and same antennas. Any differences in signal would be due to propagation and distance.

The basic idea of Argus is to be able to look in all directions at the same time, thereby increasing the chance of detecting transient signals. Big Ear had detetected some transients (the most famous being the WOW! signal) mainly from the direction of the galactic poles, but considering that it would take Big Ear several years to survey the entire sky the detection of such transient signals is pure luck. An Argus system, however, can survey the entire sky (by this I mean what is visible from a given location---you would need one in space to see everything) in one day, theoreticaly.

Hi Richard,

In support of your veiled supposition, yes a solar cell will emit light. Of course a Lot Of Crazy Folks will then bluster in outrage that IR is not light. As Thoreau would posit: "A foolish consistency is the hobgoblin of little minds." The greater consistency is found in that a solar cell responds to the 90% of the sun's spectrum that is unseen.

Pick up any LED (which is visible light, I will leave that determination to the individual), connect a meter to it, and point the LED at a light source (which is visible light, I will leave that determination to the individual), and low a potential will be developed (typically the commonplace 0.7V, but this varies with LED color). I have also observed this in common diodes - LEDs merely have optimized their junction for maximum visual exposure.

There is nothing in this to suggest that efficiency follows reciprocal use. The hobgoblins would be loath to admit that the light bulb also serves as a light detector - even if poorly (but superbly for RF Power level measurement).

>~ 900MHz)?

Hi Harshana,

The simple, conceptual answer is that length is one fourth (ï¿½) of the wavelength you wish to use. To get the wavelength, divide 300 by the number of MHz. This size of antenna requires a "counterpoise" of roughly the same dimension. An example is a plate or ground plane that is ï¿½ wavelength in any direction from the bottom of that antenna. You may notice that those cheap remote control toys probably do not exhibit this characteristic. However, if you remove the plastic shell and observe where the antenna connects, there is some conductor or PC board of enough length (and probably less) to serve.

The elaborate answer is that beyond the simple answer, you are optimizing the antenna to obtain the last 20% of the available efficiency. Optimization is NOT typically found in toys - however, it often does not make any difference (20% is unremarkable).

I should have said the resulting number would the length in Meters.
For example with your
400MHz = 75cM
900MHz = 33cM
the elaborate answer would tend toward:
400MHz = 71 - 72cM
900MHz = 31 - 32cM

I still have my PDP10 programming manual. Jeez, I --AM-- OLD!:-)

Yes; Bob had a great idea.

I suspect it will take 30 years (from now) to do this properly, get all the birdies out; get a nice patch of land in Arizona or Utah; build the system;find ET's; and so on.

Pioneering doesn't seem like that to contemporaries. We all need lasik!

Harshana, I'm sorry for your loss, *NOT* for anything the United States Government or our troops or our liberation of Iraq did. Some warped apolgetic whining socialist thinkers blame everything on America, or our government. You can however, thank America for everything your brother had a chance to do - to go help innocent people from which even Red Cross, Crescent Red Cross and all other relief agencies faced attack from by the islamic bastards that want to destroy all other ways of life but their own.

This group has fun with off-topic posts once and awhile, but we usually stay away from political garbage that infects most other lists. So Richard, if you will kindly put your sword away (or use it somewhere people go to bash our government and our president, which you so enjoy doing) then replies of this nature will also cease. And I'm sure everyone will be happeir and get back to antenna improvements.

Best regards,

Jack Painter

Hi Jack,

And remove your opportunity to swing a rusty razor blade? I notice
reciprocity rules even when resistance is offered. I also note the
irony of suppressing such statements as I offer to reduce the chatter,
by offering the increase of chatter in like statements as bait - you
caught this fish! ;-)

I am currently listening to a Lewis Lapham talk put on by our local
"Town Hall." He offers how our "mission" against terrorism was
blighted by the comedy of ceremony in "anointing" the head of the
office of Homeland Scrutiny.

During the swearing in, they wanted to emulate the literal act of
religious anointment, usually done with a sacred oil. Instead
Clarence Thomas smeared Crisco on Tom Ridge's forehead. In a
religious community this would be called a perversion. In a
pluralistic society it is called comedy, or in deference to the actual
consequences, a tragi-comedy.

To return to the neo-con Philip Gold's observation about the war in
Iraq (at that same "Town Hall" last week): "a total disaster of
historic proportions" led by a crew of social misfits.

In a meeting last night (nearby that same "Town Hall") we watched a
film "Unconstitutional" that showed the major crafters of the Patriot
Act (Both Republicans and Democrats in a bi-partisan and FULLY
endorsed bill) who stood up in outrage on the floor of the House and
Senate to protest the wholesale substitution of law. The act had been
wholly reprinted with widespread changes in text at 3:45 AM and voted
on at 11:45 AM. NONE of the text of law passed by committee was in
that bill. As the Republican in charge of the committee offered "no
one read the bill that was voted on." No one except for the members
from Georgia (Republican) and Oregon (Democrat) - presumably both
being noted "crypto-commies" (the quote of choice from a commencement
speech by Cheney).

Is there such an animal? I am going to use this rig totally portable (beach, backyard, woods, open field) and would like to make or purchase a tuned vertical for thirty. I will be using it with an oak hills portable cw rig. What do you think?

Normally, print option should be included/listed under FILE or in this case under WIRES. It would also help to have SAVE AS in ascii file or whatever.

Richard outlines the idea of organizing the options well.

I actually got around it by using MultiNEC, into which one can import EZNEC data and then use it as a spreadsheet with print selection of the sheet. K7GCO asked me how to print wire list and that created the question.

Cries? Heheheh...looks like you are the keyclown whining in your frustration. How does it feel to know that you are powerless to stop AKC dissent. There is nothing you can do, sidewalk sissy...nada...and we just keep proving it. Happy Thursday, maybe we SHOULD put you and sidewalk sissy Chukkee on pay per view....putya in a ring and have the judges decide the most limpwristed of the 2 of ya. HARDEEHARRHARRHARR. Man, the AKC could clean up by selling feminine hygene and baby toy ads on the show, not to mention auctioning off the winner's pink tights on ebay...woo hoo...I KNOW keyclowns would bid that sucker up!

3601. Re: 30 meter qrp vertical

go to rat shack and buy a couple 25' rolls of hookup wire, put one vertical
and the others horizontal. hook the vertical one to the center of the coax
and the horizontal ones to the shield.... voila, instant vertical... trim to
make rig happier as needed.

Dave,
Thanks so much. One question, do I use a 25' section of pvc to keep it upright? Also, should I trim the vertical or the horizontals for swr?

Thanks
Greg

Hey Doug, just a question...how long you figure until you do a complete meltdown again and start posting porn related garbage? I know in the past, you don't have much tolerance for being made a fool of, but I was just wondering if the COURT ORDERED helped you any.

Take care guy, and I'm glad you can't afford a trip to Texas, otherwise I'd have to watch my back.

BWHAAAAAAAAAAHAAAAAAAAHAAAAAAAAA!!!!!!!!!!!!!!!!!!!!!!!!!!

Subject: Anyone know a referral site for Doctors specializing in dementia?
This is the only article in this thread
View: Original Format
Newsgroups: alt.dementia
Date: 2001-02-20 14:28:08 PST

I need a referral source for doctors specializing in dementia around the
Toledo area.

Hi Richard,

Who cares what town hall meetings you listen to? Unsubstantiated crap or the word of God, on a list where it belongs, or in personal e-mails, you'll find a sword's edge you have to reckon with, but you waste everyone's time in rec.radio.xx telling us about it. You have so many valuable opinions and expertise in several areas, but you're a common flamer when it comes to this newsgroup lately. Nothing I read in hundreds of your posts before had such diversions. Will the real radioman please come back?

Best regards,

Jack

It does not need to be cut, just wrap it around itself on the insulator
side.

Hi Jack,

My posts number in the thousands (nearly 10 of them in 10 years).

As for choices in what to post, I responded to BOTH the issue of an antenna AND the comment of Iraq. I would note you and Jim both have chosen NOT to comment on antennas and ONLY about the political scene.

If your desire was to reduce chatter, how is it that the two of you perpetuate it? I am not particularly cowed by such flaming, nor am I impressed by supposed nobility in newsgroup purity.

I respond to issues that demand analysis. I put up examples and note their correlation. When I get flak that constitutes nothing more than "t'ain't so" I am satisfied the point remains unchallenged, much less untoppled.

I have offered authorities on the subject from BOTH sides of the aisle. (I haven't even yet mentioned what Cornel West had to say.) I perceive nothing but denial from your comments or the grief of illusions shattered. I've probably heard more Republicans say ditch Bush (Bill Ruckelshaus and Russell Train two weeks ago) than Democrats. I've probably registered more Republicans who want to kick Bush out than Democrats who want to elect Kerry.

One speaker offered he could respect Barry Goldwater who found the neo-cons a bunch of effete hypocrites (they all come from the left-wing if you weren't aware). The speaker offered Barry was a lone wolf when he went against the establishment - now the Right Whiners are a herd of sheep.

3610. Re: 30 meter qrp vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-23 21:44:17 UTC
From: Dave <noone@nowhere.com>
Message-ID: <2qCdnR4h-eog3s7cRVn-qg@crocker.com>
Source record: 89181

use whatever you can to hold it up. throw a rope over a tree branch, run it to the peak of your house, whatever you have tall enough... don't have anything tall enough? stand up as much pvc as you can keep upright (25' probably won't stand up, but 10-12' might) and spiral the wire up the pipe.

trim the vertical wire for swr... though trimming the horizontal ones to the same length may also help, especially if they are elevated above ground. if they are sitting on the ground then trimming them will probably only have a small effect.

It is more like what is accepted convention in organizing the programs and menus. Menus can be intuitive and as used elsewhere, or in the form of mystery chase. Normally, programs allow to print the contents of the window just by going to FILE and PRINT and active window is printed. No need to aks questions on the NG :-) You know how it is with manuals - they are for dummies, we are smart. :-)

Roy, W7EL wrote:
"And a 1" square solar cell is about 50,000 wavelengths on a side."

Yes. The wavelength of light is so short, about 1/50,000 inch according to Roy, that it is measured in Angstroms. The Angstrom is about 10 to the minus 10th power meter.

My question is why anyone would want to produce micro, micro antenna arrays when the LASER produces a narrow, uniform, high-intensity beam of light of one very pure color (frequency) that can be directed in a very thin concentrated beam over short and very long distances. Maybe there isn`t such an efficient receiving device?

LASER (light amplification by stimulated emission of radiation) light can be so intense that it can vaporize the hardest and most heat-resistant materials. Can`t a receiving LASER be locked in-step with external synchronization to provide necessary gain and selectivity?

I wrote: "Electricity does not travel through a void. Fields travel through a void."

Electrons do travel through voids quite readily. Note the display on a CRT. They take advantage of the emptyness not to colide with matter so they can continue their flight. There are also countless electrons wandering in space between the heavenly bodies, but not so many as to provide a conductor.

What I meant to imply was that an EM wave does not consist of actual volts and amps until a conductor intervenes to have the fields generate the volts and amps on it.

Even more trivia:
My work at the Big Ear under W8JK years before N8EE's work involved the first digital recording of radio astronomy signals including time information. (Slave labor, AKA graduate students, were used previously to digitize the strip charts used.) The recording medium was punched paper tape and the (very off-line) processor was an IBM 1620 (or something like it - it was a true decimal machine intended originally for accounting - some arithmetic operations involved table look up!). It took several orders of magnitude improvement in computational power and in ancillary equipment to arrive at what Jim was able to do. I delight in that progress.
Pertinent to this group, is the admonition that one still needs to understand the analog part of any such information gathering system even while digital power increases. At least within my remaining lifetime, the antenna(s), transmission line(s), and "first stage" will remain the province of analog engineering. This group will have plenty to discuss before it is supplanted with an A to D converter!

Hi Richard, you are starting the flames of issues not asked here, and doing a boring job of it at that. It is impolite to make unsolicited replies to an individual's email, so we punish the group for it. Proud to be part of that, I'm not. You haven't read anything that most of us here haven't already or couldn't if we wanted to. Whatever your education in political science is (it was an 18 credit minor in college for me), you seem unaware that there isn't a debatable difference between the Republican and Democratic Parties today. Rhetoric aside, and that means ignoring the speakers you love to reference as well as all pre-election babble, I'm going to offer that if you want to debate something here, shift a thread with [OT} in the subject, and then pick a topic you have real interest in, not some speaker/flavor of the day that blew your skirt up on the radio.

>
> One speaker offered he could respect Barry Goldwater who found the

This is exactly what I'm talking about. No connection to anything, stereotyping without factual reference or relevance, and closing with an opinion you obviously like, but which differs with millions of people who are well educated and very committed to understanding and explaining conservative principles. Assuming you really desire to make a contribution to solving America's problems, then knowing America's strengths, and how we got here, is of course a prerequisite. I consider the choice of experts which you consider quotable to indicate you are lacking in those fundamentals, offering a weak attempt to impress others with your street knowledge of the hacks-of-the day.

A vertical wire about 23' to 24' high will give you a 1/4 wave
vertical antenna for 30 meters. Add several radial wires of the same
length to spead on the ground, and you should be good to go. Feed with
coax.

The vertical wire might have a rope and a small weight on the free
end, to hang the wire from any handy limb.

There's a handy vertical antenna calculator at
http://www.csgnetwork.com/antennagpcalc.html

Hi Richard,

That wasn't very apropos of anything without some correlative. One such is that as a consequence of that size (in wavelength count), the cell exhibits a Lambertian shaped distribution for radiation response characteristic.

>My question is why anyone would want to produce micro, micro antenna
>arrays when the LASER produces a narrow, uniform, high-intensity beam

Someone may choose to replace the LASER by such an antenna grid, but there is a world of other choices for their effort that LASER does not enter into.

One such application, that I have offered here in the past, is a conjugate mirror. Researchers have designed one in the RF mm wavelengths. Nanotechnology has the promise of shrinking that dimension to the visible light wavelengths - using DNA base pairs for structure if they chose. ;-)

In a sense the conjugate mirror is the reverse analogue of the LASER and would work quite well with LASER emissions. In fact it could enable a new class of LASER construction.

Hi Richard,

A laser is very inefficient, power-wise.

Nano antennas may offer a cheap option for high efficiency solar conversion.
Yet to be demonstrated.

No I would not - you're totally wrong.

BUT...

I would happily remind you or anyone else to pay attention to the word VISIBLE, as in visible light, when you, or y'all, clearly neglected to pay sufficient attention (DARPA and all that IR sub-thread) to the exact contents of the CNN article and my previous postings (all of which were perfectly clear).

See the diff ?

Furthermore, you're (intentionally?) ignoring my previous Position Statement: "I'm as in favour of the fundamental sameness of light to radio waves as anyone." Given IR's position in the spectrum, you can easily derive how I feel about its nature.

Your comment (top) was unfair - almost mean.

<sniff> <-- ;-)

Hi Jack,

This is a curious complaint as I review your past correspondence. For more than a week it constitutes basically non-antenna discussion with a vengeance: The date format on should it be 9/11 or 11/9; firearms and gun control for 7 out of 8 postings by you in "half-wave dipole in the forest"; a lob against the school system; and 3 here in this and the original thread.

Lately you seem to be quite bored with antennas. Others can compare my choice of subjects responded to, and how well. To this point, one nameless canuk takes issue and I note your absence in all of those discussions. Should we continue with what Cornel West had to say? :-)

> It is impolite to make unsolicited replies to an
>individual's email, so we punish the group for it.
shows an odd reason to create your own topic. Further, your statement, as intriguing as it is, doesn't make any sense on the face of it.

>This is exactly what I'm talking about. No connection to anything,

And one wonders how you can both complain of it, and simultaneously offer so much of it in the same breath.

Chip:
Amen. An objective of most who teach in the area is to nurture students who are able to discern when it is analog time and when it is digital time. The allure of digital has to be mollified. Occasionally one has a student who's eyes light up when he or she is exposed to the art of analog after seeing the science of same. Many more students are appalled.

It has been one of the pleasures of my life to collaborate with a wonderful colleague (and extra class radio amateur) as a catalyst and teller of stories while he puts down some of the accumulated analog wisdom reinforced by his analysis, insight, and exposition. No doubt some was acquired in this group. Look for his encyclopedic book from CRC to be available within about a month.

I recall that when questioned about some past apparent wrongdoings, in most cases the reply was "that's old stuff, we have to move on". So your SUMO sounds about right.

Funny how that *wasn't* the case when they wasted millions of our dollars chasing Whitewater.

Go figure!

Hi Mike, well my first 2 years of undergraduate *were* at Penn State!

> But I would like a *candidate* that a *conservative* could vote for!!!!
Yes, we knew we were in trouble when Christine Todd Whitman said "It's my
party too".

> Neocons just strike me as Liberals with bad tempers.
The Michael Moore syndrome?

> People argue Republican vs. Democrat like they do Coke vs. Pepsi. The

> acid.

Check out Pat Buchanon's book "Death of the West". Then thank folks like
Richard that *want* to be conservative, but because their eyes suddenly open
to hypocrosies in Republican administrations, they blow their bugle of
reteat (from the *rear* of course) leaving us standing up on the front lines
alone. Meanwhile they aid and abet the enemy by leading attacks against us.
In truth, probably the last thing he really wants is to harm his country.
But definitely the least kind of person in the world you would want in a
foxhole with you!

Hi Richard, nope - and I'm actually erecting that center-fed inverted-L this weekend for 2182+ coverage. The advice and help I have received from this group (and especially from you) is appreciated. I picked up the materials today at Radio Works in Portsmouth. They suggested I try a bob-tail curtain if the L doesn't work out. I don't know anyone using that type of antenna on a small scale (we have a rather monstrous one at work, but it is designed as a cloud-warmer, out to 300 miles coverage).

Jack

hello,
no joke. i am really interrested in, because i have build a very simple
eh-antenna(microvert) and i have done a few dx with this antenna abt. 3m
over the ground. (you can see it at www.ronald-winkler.de) a few weeks
ago i could not believe, that it is work. but it do. so i am looking for
other small simple antennas for the lowbands.
thank you.

Check out this portable vertical. Looks great for the beach, camping, etc

http://members.aol.com/realhamradio2/W2IK-ANTENNA.html

I have not built one yet, but I am planning on it this weekend.

I use a K1, Norcal 40A, or DSW II on 20m when I hit the outdoors.

This antenna covers 10 - 160 if you follow the intsructions. I'm making
mine for 15-40

Hi,

New at this.

Do sw listening only (no transmitting) up to 30 MHz.
Like to listen at most all freq's.

Have a random-length simple wire strung around the 4 sides of the attic.
Same wire is fed down a floor into radio.

It's open at the end; NOT connected back to beginning of attic run to form a
loop.

I know I can try it and see, but frankly it's getting hard for me
now to crawl around up there.

Would you expect better performance if it was formed into a loop ?
Why ? (what "theory" or eq's would apply ?)

Thanks,
Bob

i would do lots of very detailed calculations, lots of computer modelling, and measure it with every instrument i could find to be sure it has exactly the pattern predicted and the right impedance across the whole hf band so the receiver would work properly. then after months of computing and modeling and measuring i would hook it up and it would work the same as it would work if i had hooked it up without doing any of that. a random length wire, in close proximity to buildings with wiring and other unknown metal stuff can not be adequetely modeled over even a small range of frequencies, let alone 'most all freqs'. so hook it up and try it, if it lets you hear what you want then leave it alone. if it doesn't then try adding another wire out the window or around the floor or hook up your bedsprings.

Art,
'How' you think of, or envision a particular antenna is entirely up to you. But, when you want to communicate your thoughts about that antenna to people who do not 'envision' antennas in the same way that you do, you have to use commonly acceted means/terms. If you don't, there will always be misconceptions/errors in understanding what you are trying to say (doesn't matter if the 'what' is correct or not). I think the problem is in the 'translation'.
'Doc

It's still a nickname. I didn't 'pick' it, it was given to me. It doesn't mean I'm a 'doctor' of anything (I'm not!). Sorry if it still bothers you, get over it.

==========
Ron, my guess is that none of the replies to your question are from people who have ever used or have even seen the antenna.

With plenty of idle time to spare they are just repeating old wives' rumours for a little mischievous amusement.

From its construction I estimate its performance to be marginally worse than a magloop of the same physical size and operating frequency. And magloops don't do too badly, do they?

Reg

Doc, You may be correct but if people are hanging around with a stone in
hand
eventualy they are going to throw it. But no matter, since the programs use
is not
clear to me it is unlikly that I will use it.
On the subject of "loops" I see them as a parallel circuit enclosing a
sufficient area
for radiation.The inherent capacitance and inductance and/or with added
lumped
portions of the same creating a path for current for radiation...
This is in contrast to a "stub" that is devoid of an enclosed area or a
"trap" that
blocks the flow of currentat a given frequency.
.Nuff said on this subject
Present focus is on following the thread where Richard the shark placed bait
for
another stone throwing contest and caught another netfull of unknowing
fish to hit upon..

One of the concepts that I have had trouble getting 'younger' engineers to understand is that a digital signal >>>IS<<< analog! Just because you are running at "only 10 MHz" doesn't mean that you can have 4 inch pigtales. The actual signal bandwidth would extend up to 50 MHzor even more, and you have to treat it like a VHF/UHF RF signal or the bits are going to get lost. Digital is Digital only in the purely logical sense (pun very much intended, by the way).

As for digital signal processing is concerned, just because you have digitized the signal doesn't mean that you have eliminated all of the analog problems. I can think of only three ways that DSP is better...1)no cross talk in signal paths, and 2) lossless signal duplication (think of an analog power splitter), and 3) you can do things easily that previously were just a glimmer in an analog engineers eye (such as multiple simultaneous beams from an antenna array?)

Hi Guys,

This reminds me of the problems I had teaching the digital types
Shannon's law for BER.

When I designed the black box for the 757/767, all of my digitized
readings (taken from 600 leads) was passed over to a specialized tape
recorder (25 hour capacity).

Problem was that this digital signal was fed into the recording head
without any bias. Many may be unaware of the advances in audio tape
recording BW that came by the addition of bias, and more, that it
reduced the head's tendency to erase its own stored signal. In
essence, with no bias, you were recording data with two strikes
against you. This was not the hallmark design for a data sensitive
product. Worse yet, was this digital mentality had recorder
specifications that allowed for a S+N/N of 2.

What were the comments I heard in response? "This is not HiFi, it's
digital data, on/off."

Within weeks I was drawn into their simulator lab to view a simulated
cockpit of an KLM aircraft that was being used to display flight
recorder data that was rather -um- noisy (much too much for KLM's
engineers to make sense of it). I watched that plane hit the ground
several times as they struggled to recover digital bits lost in analog
noise.

Several (many) years later I was called to consult on the TWA flight
800 data - more noise that lead to hints of missile strikes. The
panel's best spin on the topic was that it was old data printed
through the new data (even though the difference in time would not
correlate to the two data sets overlapping). We reported it as
exploding gas tanks, Tehran reported it was revenge for our shooting
down one of their civil aircraft during the first Gulf War. Like the
first attack on the Twin Towers, government and the media shrugged off
correlations.

3658. Tohtsu coaxial relays - anyone using?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-24 20:35:45 UTC
From: Floyd Sense <fsense***@risp.biz>
Message-ID: <cj21at$25i$1@news.chatlink.com>
Source record: 89079

I picked up a couple of new Tohtsu CX-600M coaxial relays - they are similar to the DowKey relays, with three UHF connectors of the SO-239 design. I had a problem screwing on the PL-259s more than 3-4 turns and in checking the threads I find that the pitch or threads-per-inch of the Tohtsu connectors does not match that of the PL-259/SO-239 UHF connectors. I wonder if anyone else has run into this problem? I was under the impression that the UHF connector was a universal item, but maybe that is not true?

Tohtsu web page (English language version)
http://www.tohtsu.com/index-e.htm

Here are the specifications for this coaxial relay from the Tohtsu web site
(isn't the Internet great, electronic library in you house).
http://www.tohtsu.com/products/cx-600m.htm

Henry Radio sells these (new)
http://www.henryradio.com/Tohtsu/cx600m.htm

Invented in the 1930's by an Amphenol engineer named E. Clark Quackenbush,
UHF coaxial connectors are general purpose units developed for use in low
frequency systems from 0.6 - 300 MHz. Invented for use in the radio
industry, UHF is an acronym for Ultra High Frequency because at the time 300
MHz was considered high frequency.

Source record: 89081

Oh my goodness! No bias! Wow.
Both Jim's and Richard's observations are the sort of things that need to be
told to budding engineers.
I tell quite a few stories in class. After all, engineers kill people
with their mistakes in wholesale lots. Stories, since well before writing,
have been the way to communicate the important "stuff." The black box story
needs to be told. I effect some of Jim's story with the (apparently) simple
lab job of connecting N CMOS inverters in a ring - and then "playing."
(Fortunately, we have very high bandwidth scopes in each workstation so that
clues to what is going on can be seen. Thanks to a generous grant from a
company formally known as HP, we can see spectrum too.)

Many thanks for your contributions.

Thanks, but I've already covered that ground. The connectors are not threaded per the specs. I reported the problem to the dealer, and they told me that after checking their stock, they found that about half of the relays had incorrect threads on the connectors.

So, if anyone is in the market for a coaxial relay and are considering Tohtsu, make sure that the seller tries a PL-259 on ALL THREE of the connectors on the relay. Hard to understand how a reputable machine company could make such a mistake, but it happened. The dealer, Nebraska Surplus Sales, stepped up to the problem immediately and is doing the right thing.

Floyd -

I have heard of this problem from overseas mfg. (getting the 5/8 - 24
threads correct) .. which I am sure is realted to being more familair with
metric and not having the tools properly calibrated for English !

Glad to hear you are getting support for it. Another reason to consider the
Dow model 60 series for usage.

I have for sale a 40ft tower. I believe it may be a Rohn 25, it has
the bottom section which was cut off at the base, so its not quite 10
ft, 2 full 10ft sections and the tapered top section. This is a guide tower
and is NOT self supporting.
If your interested please email off group. If you like I can send u some
digital pics

thnx

3671. Half slopers for 160 and 75 on one tower

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-25 19:29:41 UTC
From: Roger Halstead <Delete-Invallid.groups@tm.net>
Message-ID: <qbhbl0l38h3qmlogcks6rfr75prqs4val4@4ax.com>
Source record: 89092

Yesterday I installed a half sloper for 160 with the top end anchored
near the top of my 97 foot tower. It could be beginner's luck, but
the thing works great.

I currently have two 75 meter half wave sloping dipoles (NE and NW)
which work very well, but the coax and baluns make them sag
considerably in the center.

I'm thinking of changing the 75 meter antennas to half slopers and
interspersing them with the 160s. IE...160 and NW, or would I be
better off using a lower attach point for the 75 meter half slopers?

Any one have any experience with these and any suggestions...before
the weather gets really cold.

I regularly use an active 41" monopole to accurately measure electric field
strength over the range of 10 kHz to 30 MHz. That's a ratio of 3000:1, and
that is 25-year old technology.

Source record: 89098

It's no concern of ours, the rest of the World's 5 billion population, that 10 or 20 thousand Americans kill each other with firearms every year. What bothers us is the naturally aggressive tendency of Americans to export the habit of using weapons of mass destruction in futile attempts to educate people in the so-called American way of life.

Witness the mess in ex-Yugoslavia, Iraq, Palestine, Afganistan and numerous other places in this small world.

All activities in that direction are directed towards American energy interests only. Can't say that I blame you. It's human nature after all. But it's hardly altruistic as your politicians frequently claim.

But of course, it is not the ordinary American people who are to blame, it is just their multi-national corporations, their dishonest banks, their oil and energy companies, their pharmaceuticals, their tobacco and junk food industries, atmospheric polution, the armament industries, and the secret police, the 'unreliable' CIA information departments, etc., which constitute the problem.

Sort *them* out and the whole world will be a happier place and will thank you for it. But you've got an immense job on your hands. Terrorism is just a sideline which causes fewer problems than street traffic accidents and antique gun laws. Get things in proportion.

Just another foreigner without a vote in the forhcoming presidential election. But which affects me nevertheless.

Good start Harold! Allow me to pick up with it from there....

Reg, you also wrote:

"But of course, it is not the ordinary American people who are to blame, it is just their multi-national corporations, their dishonest banks, their oil and energy companies, their pharmaceuticals, their tobacco and junk food industries, atmospheric polution, the armament industries, and the secret police, the 'unreliable' CIA information departments, etc., which constitute the problem."

(first of all *thanks* for your personal absolution, we're relieved) <G>. But we should remind you that "our multi-national corporations" is a misnomer - they are, as you said, multi-national. Want to guess who is the biggest investor in US interests? Great Britain is, so they are "yours" old boy. And wasn't it M7 or some James Bond agency of yours that claimed there was a definite link to WMD/nuclear materials by Iraq? I know, you tell us all the time, it's George & Tony's fault, they made this stuff up at their supper club meetings. I know this is kind of unsettling for a fine chap as we know you are, but the next time you think America has some knd of monopoly on gun-toting, punked-out, drugged-out losers that actually manage to "vote" sometimes (always liberal just like you buddy), just check your London papers nce and awhile, and better yet, stroll downtown. My recollection is that London is just like NYC, NY, with a little bit of everything at any corner. As Harold said, God forbid you take that same stroll of exploration down an Ulster street during one of the little flare-ups of "the troubles". Even your police and your army riding in armor vehicles are not safe then - on your God-save-the-Queen Great Britain streets in broad daylight. My point is that in your own country you've got some of the most hideous examples of human behavior found anywhere in the world, even if you haven't chopped heads of (yet - your skyrocketing muslim

populaton cannot be far behind that plan). But most of us would argue that the begging-for-death tortures perpetrated on victims of your "troubles" might have been better off dead than suffered the circumstances of your british honour among terrorists.

I have found that this reduces low frequency pick-up. Loops need to be approaching 1 wavelength around to work efficiently, whereas the wire would be OK as a 1/4 wave.

As to whether the signal to noise ratio will be better with the loop - well you'll just need to experiment ;)

Reg, G4FGQ wrote:
"Just another Foreigner without a vote in the forthcoming presidential election. But which affects me nevertheless."

The U.S.A. affects everyone on earth due to the size and vigor of its economy and the development of its industry and military.

Anyone and everyone are concerned about forces in the neighborhood outside of their control.

Europeans suffered from crazy bloody wars long before Columbus found a "new world" across the sea. Warfare was not an invention of the U.S.A. To survive, a nation must become very good at war.

The U.S.A. was first to produce nuclear weapons and the intercontinental missles to accurately place them on target.

The 19th Century was dominated by the British. Two world wars followed by a cold war were the heritage of The British Century, that was experienced in the the 20th Century.

Twice in the 20th Century, the U.S.A. answered desparate calls from Britain and France to send Germany and its allies back to their homes.

Perhaps Britain and France could have done more to avoid the 20th Century conflicts. The U.S.A. had the least to do with establishing boundaries which have resulted in constant warfare.

President Hoover who had seen European operations while trying to feed Europe following the first war to end wars in the 20th Century, argued the U./S.A. was foolish allowing itself to become involved in Europe`s struggles. Hoover was committed to minimal involvement in foreign disputes. During the Hoover Administration, the U.S.A. was self-sufficient in oil and other commodities as a supplier and as a customer.

Then the great depression hit. The world owed the U.S.A. for the WW-1 weaponry supplied by the U.S.A. on credit, but only Finland paid. Times were tough and business wanted to import from cheaper sources and to export to markets that paid more than the U.S.A.. There was little interest in Hoover`s isolation.

Reg says: "Witness the mess in ex-Yugoslavia, Iraq, Palestine, Afghanistan and other places in the world."

Reg is blaming the Fire Department for the fires. It was not the U.S.A. which Balkanized the Balkans. Nor, was it the U.S.A. which partitioned Palestine. Nor, was it the U.S.A. which promised the Jews a homeland if

they would only support the Allied Cause in both world wars. Nor, was it the U.S.A. which tried to anex Afghanistan. Nor, was it the U.S.A. which tried to maintain a colonial control on French Indo-China in the face of advancing communism. Nor, was it the U.S.A. which insisted on selling dope to the Chinese when their government was dead set against it. As a former colony itself, the U.S.A. had no sympathy for colonialism.

Despite popular condemnation of the U.S.A., there is no great exodus of deserters, but instead there is a clamor from people the world over dieing to get in the U.S.A. by almost every imaginable means. As a person who has seen most of the world, I think the U.S.A. has come closer to the ideal place to live than any other place. Millions share my opinion. In fact, mavbe billions think the U.S.A. would be the best place to live despite the disadvantages of not being a native. If we in and from the U.S.A. must shoot a few punks to keep what we`ve been able to establish and keep so far, well that`s just too bad.

We are better because of free access to guns. Remember Sgt. York in WW-1? Well we had many other sharpshooters in WW-2 and other wars too! Many have been shooting real guns most of their lives.

Best regards, Richard Harrison, KB5WZI

3684. Yeasu ATAS-120 trouble

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-26 07:49:10 UTC
From: WG <nojunk@mail.com>
Message-ID: <Wvu5d.156280$XP3.7129@edtnps84>
Source record: 89105

Hi All

I picked up a Yeasu ATAS-120 antenna for my Chevy Metro and my FT-100d. The trouble is that I can't get it to tune on 40m, 20m 10m and 6m. It has no trouble on the rest. I have tried different locations on the car and the mount is screwed to the front fender and no luck. Anyone else have this trouble and how did you correct it?

Thanks in advance

Hi Richard,

This is not entirely true, but I will pick that up below.

>Then the great depression hit. The world owed the U.S.A. for the WW-1
>weaponry supplied by the U.S.A. on credit, but only Finland paid.

You should add that only Denmark paid their war debts for WWII while DeGaulle gave us the boot and the rest stubbed their toes in the dirt when this embarrassing question was brought up.

>Reg says: "Witness the mess in ex-Yugoslavia, Iraq, Palestine,

>
>Reg is blaming the Fire Department for the fires. It was not the U.S.A.
>which Balkanized the Balkans.

Well, we were very closely involved through the agencies of Wilson's crew of young and up and coming savants he called "The Inquiry." This crew met in secret (sound familiar?) as the CFR (Committee of Foreign Relations) whose British arm was called the Royal Institute of International Affairs.

Members of the CFR included (familiar names only): Allen Dulles, John Foster Dulles, Christian Herter, Walter Lippman; and (unfamiliar names, but noted specialists): Dr. Isaiah Bowman, Chief Territorial Specialist. American Geographical Society; Dr. Clive Day, Regional Specialist for the Balkans; Dr. Charles H. Haskins, Regional Specialist for the northwestern frontiers; S. K. Hombeck, Regional Specialist for the Far East; Mark Jefferson, Chief Cartographer; Douglas W. Johnson, Specialist in Boundary Geography; Dr. W. E. Lunt, Regional Specialist for Italian boundaries.

Having heard of this group from both the left (Lewis Lapham, Harpers) and right (Phillip Gold, "Taking Back the Right") - if we weren't responsible for the Balkans/Middle East it is only because we didn't try hard enough nor fast enough (or simply allowed surrogates to accomplish the same agenda - AKA RIIA). Anyway, from the list of map makers and boundary experts above, it is obvious we weren't looking to document the return of the Elgin Marbles.

>Nor, was it the U.S.A. which
>tried to maintain a colonial control on French Indo-China in the face of
>advancing communism.

From "The Viet Cong Insurrection Manual...," Gen. Vo Nguyï¿½n Giap:
"The French Imperialists were getting more and more bogged down
in their unjust war of aggression. American aid, which covered
15% of the expenditure on this war in 1950 and 1951, rose to 35%
in 1952, 45% in 1953, soon to reach 80% in 1954... [Dien Bien Phu
the most heavily fortified bastion of the French was wiped out
8 May 1954]"

Much of this was validated independently by American sources in the
mid 1960's and a source of several books by William Lederer and
Eugene Burdick ("The Ugly American," "Sarkhan").

>
>We are better because of free access to guns. Remember Sgt. York in
>WW-1?

I remember Howard Hawks' treatment of him as the Pacifist (Quaker) who
killed more than 100 Germans (played by Gary Cooper). In fact MANY
movies present Hawks with an hommage through the inclusion of the
sharp shooter licking his thumb to clear the front sight of his rifle
(it is done by John Dall in "Gun Crazy").

There are few here who probably are aware that the Iraqis are
GUARANTEED by our military the possession of an Assault rifle, one
each for EVERY adult in the household. Phillip Gold has offered this
is the bare necessity for them to survive their own tribal conflicts
(Iraqis have absolutely no sense of nationhood).

Here in the Peoples Republic of California, you can't even have a weapon
that LOOKS like an assault rifle. Because of that, we are respected the
world-over for being the safest region of the USA.

Meanwhile, did somebody forget to tell the Iraqis that they were supposed to
turn in all RPG's? Or maybe they just didn't understand the turn-in process?

Here is a link to a prior art antenna device comprised of carbon nanotubes.

I am surprised so many hams do not distinguish between antennas and devices like photodiodes.

A nano-antenna can be used without a lens. Groups of nano-antennas can be used to make gain antennas, directional antennas, and steerable antennas, but you knew that from the ARRL Antenna Book. Antennas can be connected to junctions that can then detect, mix, modulate, upconvert, downconvert, and the antenna elements can be tuned to length so they favor certain wavelengths. Lots of information can be sent.

Lightwave-scaled antennas can be biased to switch light. They are quite fast!

There is also a shortening effect that hams already know about at radio wavelengths that is more pronounced at light wavelengths, essentially due to the inertia of the electron. Even so, practical antennas can be made by growing them to length on a substrate, such as silicon. I have been working on this since the mid-90's.

Oh, the links

www.ambitcorp.com

has a list of some prior art patents in that area.

You can also look up W1XYZ in

www.qrz.com and see some more stuff that is related.

IBM's Phil Hobbs may be putting this to work to try to eliminate board to board or chip to chip interconnects which is a worthy goal. Phil is right as we did our first demo about a decade ago. How time flies.

Does an 88 ft. doublet have any advantage over a conventional 67 ft.
doublet? In either case, feedline would be approx. 50 ft. of 450 Ohm ladder
line to a 4:1 current balun, then a short length of coax into the shack.

My usual band of choice is 40, but I'd like to become more active on 20 and
30.

Me too. I'm not sure if they've 'lost it', or if they're just playing
troll.

> Here is a link to a prior art antenna device...
> www.ambitcorp.com
> has a list of some prior art patents in that area.
> You can also look up W1XYZ in
> www.qrz.com and see some more stuff that is related.

(It would be slightly more fair if you had included an advance disclaimer
that the link was to YOUR company. Not a serious issue, but it took me a
minute to realize that you're referencing your own work (or that of your
company). Interesting links just the same...)

By their very nature (especially American) patents are intentionally not
forthcoming about what has actually been accomplished and what might be
claim-stretching brochure-ware. Can you please confirm exactly when (year)
you achived an actual physical embodiment of a functioning carbon nanotube
antenna with dimensions corresponding to visible light? I'm sorry if I seen
to be poo-poo'ing, but I didn't see that precise question answered on the
provided links. I did see mention of larger structures. A more-precise
link would be helpful in this regard.

If you can do that, then I'll award you the 'mythical $50k' and admit
defeat.

Also, the group that was mentioned on the CNN news was from Boston, MA and
you appear to be from that same area. Any relationship between these two
(?) groups. Have you ever had contact with them on this topic?

> Phil is right as we did our first demo about a
> decade ago. How time flies.

I'm just trying to establish if your links to 'prior art' are strictly valid
(in the 'been there, done that, got the T-shirt' sense) or if they are the
sort of thing (in the sense of 'close, but no cigar' sense) that happens
with ANY new development. There's always a dozen or more groups working on
the same thing at any one time, but usually only one crosses a significant

boundary first and issues press releases to CNN.

I appreciate your posting and I look forward to seeing your next.

Hi Richard, why do you assume that few of us know that every Iraqi household is allowed to have at least one weapon? It was widely publicized on all the networks early in the war. Furthermore, no one is "guaranteed" a weapon. The Swiss government guarantees (this means they provide) an automatic weapon in the home of each militia-age adult male, no other government or military that I am aware of makes such guarantee. Concientious objectors (their equivalent) must perform civil service for a period equal to compulsory militia training for all others.

Incidentally, the same exact permission given in Iraq was granted to Afghan households, and we merely continued the practice of not disarming a liberated populace.

73,
Jack

Hi Bert,

Short answer: No. [could be Yes]

Long answer: Yes. [could be No]

More details are needed to lengthen the short answer or shorten the
long answer. Are you pointed in the right direction? A longer
antenna can invalidate that. Can you load the antenna? A longer
antenna can invalidate that. Going to higher bands makes these
questions even more meaningful.

Advice: Leave it alone, or put it up higher.

From: t_ashland@yahoo.com
Message-ID: <6e6aeba9.0409260924.287c77b2@posting.google.com>
Source record: 89118

Hi! To make a long story short, I will be moving my beam to another tower, and will have a rohn 25g tower that is imbedded in concrete approximately 50 feet away from the house. I would like to get a decent lower band antenna (not 160). I'm wondering what would be the best scenario:

1. Put up a mast above the 32 feet of tower and hang an inverted V (Alpha Delta 80/40) and 30 meter inverted V (common feed). It would be up around 40 feet.

2. Put my Butternut HF2V vertical up on top of the tower and put a few resonant radials for 80 and 40 on it. It wouldn't be guyed (important here in NW Iowa). I thought about even using the 80/40 dipole as part of the radials since I already have the antenna. (Anybody have any experience with loaded radials?) My HF2V vertical ground mounted didn't seem to cut it the last two winters...

3. Load the tower for 80, 40, and 30. I would need some guidance on how to build a gamma match for this situation. If I went this route, It would probably not work well for 80.

4. Extend a mast on top, and string some sort of Inverted L's for 80, 40, and 30 and put ground radials at the base.

My primary interest is to increase my DX totals especially on 80 since I already have DXCC on most of the other bands. I have a decent antenna for the higher bands.
Thanks
Terry, WK0F

And that should be complex gain, since in the stated application you are
concerned about phase and magnitude.

Also, don't forget about the mutual coupling between elements. What happens
to it over a 3000 to one bandwidth? Remember we are talking about an array
of antennas, not a single isolated one!

Source record: 89021

Ed's one meter vertical over a large conductive ground plane has an
effective height of close to 0.5 meters up to something like 20 MHz. With
an amplifier at the base of the vertical that has high input impedance and
some tailored feedback, one can have a system that can be used to measure
field strength with very little frequency dependence.
I use a miniaturized version of such an antenna as a probe in a TEM
cell.

I have seen the use of resistively loaded (short) dipoles connected to
resistively loaded transmission lines used by the NBS (as it was then
called) to measure field strength with minimum disturbance to the field.

These are all receiving antennas with essentially uniform performance
over very large frequency spans.

My feeling is that to have a small variation in transmitting gain over
more than something like five to one will require an adaptive antenna
system. (I am assuming antennas with an "average" gain that is close to
one - no resistive loading.) 73 Mac N8TT

The array is RX only, and G/T is important for each individual element, over a broad range. You need a truly compact element that is wideband. Wideband means about the same gains and impedances across a very wide range.

Mediocre broadband RX antennas have been around since WWII.

The discussion on TX, albeit interesting, does not apply.

Also, mismatch produces dramatic signal drops without an ATU in conventional designs, such as inverted V's. The assumption has been 'no ATU' in this project, because the costs are prohibitive.

The one mitigating issue is that the sky temperature --and this system is designed to synthesize a measurement sky tempertaure with high angular resolution--increases with lower frequency (below about 1GHz) because the emission is non-thermal. Thus the signal to noise gets better in VHF.

73,
Chip N1IR

Pretty much the same thing, isn't it?

It seems this NG has gone the way of the
rest: the division between the born-again
zealots vs. the normal folks, and the resulting
degradation in human interaction. What a pity!

The zealots are unintentionally giving the
mega-corps and the mega-rich the power to
virtually run this country. Being in absolute
control of the FCC, what they will eventually
do with the radio spectrum (in the interest of
mega-profits) will not be in the interest of
amateur radio - the BPL boondoggle, is a
precursor and good example of what to
expect from an exclusively neo-con, pro
mega-corp government.

It seems apparent that every so often, we
as a people, must re-learn a valuable lesson:
religion should have no power or influence
in the politics of a democracy!

How are you Bushites going to react when
you realize you've been duped into helping
turn this country into a plutocracy -
theological or not?

Just my opinion, of course...

3706. Natural balun/Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-26 20:08:39 UTC
From: John Smith <kd5yikes@mindspring.com>
Message-ID: <cj77k70jjo@enews1.newsguy.com>
Source record: 89027

Hi, Gurus -

Shown in "Antennas for All Applications" on page 820, figure 23-17 (a) is a folded dipole which looks as if it could be easily constructed from RG58. This antenna would be appealing because of the natural balun. However, they make no mention of the required coax velocity factor nor of the terminal impedance. I tried constructing one and measuring with a vector voltmeter but the data were inconclusive. That is, I don't think I know how to make measurements like this at 440 MHz yet. It is much trickier than I thought.

In any case, can someone tell me:

- Can RG58 be used, or will the velocity factor mess up the antenna?
- What will be the terminal impedance?
- Will the terminal impedance change as the gap between the elements vary?

(I consider the "terminal" at the midpoint of the bottom element)

Thanks.

John (KD5YI)

BTW, I can post a picture tomorrow or the next day, if necessary, when I can lay hands on a computer with a scanner.

3707. Coiled coax balun

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-26 20:24:40 UTC
From: John Smith <kd5yikes@mindspring.com>
Message-ID: <cj78i80ki5@enews1.newsguy.com>
Source record: 89029

Hi again!

Has anyone tried making the coiled coax balun work at UHF? Specifically, on the 70 cm band.

In "Antennas for All Applications", they say the coil should be resonant at the frequency of operation. The ARRL book(s) do not cover this band. Using RG58 and a GDO, I've learned that one cannot leave long leads on one's coax coil as it will lower the resonant frequency drastically. Apparently, the long leads in conjunction with the coil forms an antenna/inductor/capacitor combination.

It appears to be difficult to obtain the required resonance repeatably. Or, am I missing something (as usual)?

The diameter seems to be somewhat critical. Does the diameter need to be much, much smaller than a quarter wave? What diamter would be a maximum?

Thanks for any help.

John (KD5YI)

3709. FS - FORCE 12 ZR-3 Vertical on eBay - for pick up in Denver, Colorado only

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-26 20:59:41 UTC
From: k0owo.bill@gmail.com
Message-ID: <21c32c64.0409261259.28c1a824@posting.google.com>
Source record: 89030

Hi,

I have my Force 12 ZR-3 Vertical-Dipole listed on eBay. There is a good description and a great photo of the antenna.

This is a high preformance - low profile antenna so it is ideal for antenna restricted locations.

The antenna is fully assembled and ready for use. Just plug in your coax and start transmitting. It even comes with the recommended ground mount at no extra cost.

You have to pick this antenna up at my location in the Denver, Colorado area. You will need a pickup truck or small trailer.

Click on this link to see the antenna:
http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&rd=1&item=5722807374&ssPageName=STRK:MESE:IT

If the link does not work for you, just go to http://ebay.com and do a search for: zr-3

Thanks,

Bill

Dorm room, noise hell, lighting fixtures, computers, digital devices, wall warts, power lines, distribution lines, transformers for building equipment, radios, tvs, etc. all conspire to make radio reception a bit dicy fro all the rfi produced. The wire just makes reception of all those nearby sources all the better. Try grounding to a known ground, a transformer is not likely to help, it doesn't distinguish all the noise sources from other signals. Get battery power and pull the main breaker for the building.

Hey -

I posted in here recently about active shortwave antennas - well, I managed to get 75 feet of #26 magnet wire on a perpendicular roof to my window of my dorm room, and two runs of 15' speaker wire as a counterpoise in my room. I'm getting a really bad noise problem, however - so bad that I can't hear stations on 20 meters! There's a pretty solid S9 noise floor that prevents me from hearing anything other than WWV and the major broadcast stations. Now, I know I can do better with the amount of wire I've got strung out there.

I was thinking about adding one of those 9:1 transformers or other impedance matching things for longwires; would this reduce the noise problem I'm having? Any other tips for reducing longwire noise? It works enough, but I know I can do better...

Thanks in advance.

Pending a response from W1XYZ, I'll propose that the answer is likely to be
that you're rather naive to assume that he - or his company - is that far
along with THAT technology (light antennas to replace photovoltaic cells).
I might be wrong, but I'll put it out there and we'll see.

You are in a tough spot with all the computers and other electronics
around. A common mode antenna is the worst choice for you as the S9
noise floor attests.

A small active loop in the quietest spot in your room or on the roof if
you manage it would work the best. I would be surprised if a transformer
would help you much on the wire because I expect that the antenna itself
is picking up the majority of the noise. An exception to this would be
if that 75 feet of wire on the perpendicular roof is a garage and not
other rooms full of computer equipment.

Yes, the sound of its owner swearing up a blue storm at having to get the *&%$ thing back up over "just the right tree branches"....

Been using a "random" dipole (actually configured in an inverted vee with 50 foot legs) made from insulated house wire, fed with 450 ohm line, hooked to a little MFJ tuner. QTH is DEEP in the woods and the antenna is VERY close to trees and actually passes within inches of many leaves/branches. Work mostly 40 CW but every so often will wander around from 80 to 10 CW and SSB. Sure, I'll never have a "big gun" signal with this antenna, but it works, its cheap and easy, and I can always find someone to chat with. Once and a while, I even manage to snag some pretty fair DX.

The only thing I try to avoid is letting the antenna actually touch any thing.

Good luck and good DX

Hi OM,

Use coax out 25-30 of those 75 feet. At the far end, put your
counterpoise there and thus move your input to a position remote from
that same noise (presumably in your room). At that same far end, add
a 1:1 BalUn or W2DU style otherwise known as a Current BalUn rather
than a Voltage BalUn (the distinction in this regard is important).
This will keep noise from coupling to the outside of your coax and
funneling into the feedpoint (as long as your receiver has good
shielding). It is called "choking." This will help with radiative,
local noise. You can add a second BalUn on the antenna/counterpoise
side for Z transformation, if you choose.

If the noise is conductive, then it is coming in through your power
supply (AC is carrying trash). Good ground can help solve this,
unless you are in a room on a high floor. You can confirm conductive
noise by breaking all AC and ground paths and running on battery power
(if this is an option) or connecting your antenna to a battery powered
receiver. Another option (if no battery options are available) is to
get a long extension cord and try another outlet that you can identify
as being on a separate breaker (this may not be easy in a dorm
situation). With this, you may find a quiet AC branch that is not
shared with the noise generators.

I agree with Richard.

The problem with outside antennas and noise often results from the
noise being carried common-mode on the outside of the cable
braid BACK to the antenna. Use a decoupling choke at the
antenna end of the coax. The 9:1 balun or transformer will
minimize losses due to high impedance swings at certain

frequencies--it won't do much for noise however.

Pete

Hi Roy,

Not meaning to insult, but judging from the
past, let me suggest that constructive
criticism seems to end up in your waste
basket. Here, it's obvious you'd rather
demean confused users, rather than admit
to a flaw in your program's conception.

One would assume you would have learned
something in regards to "intuitive" or "user
friendly" from the many negative comments
you've received in regards to the horribly
clunky interface of your DOS version.

Apparently, you either haven't the ability to
conceptualize an intuitive interface or you're
just too arrogant to listen to your customer's
suggestions... which is it?

Chuck, WA7RAI

Hi, Richard -

Please give me more information about the ferrites...

How many do I need?
What permeability?
Who makes them capable of 450 MHz or so?

Thanks.

John

By the time you get to UHF it is difficult to use coils. Baluns are usually
made of coax or some of the very small hard line like less than 1/4 inch in
diameter. The coax is just a fraction of a wavelength.

Try to be a little more specific. Do you want a beam, vertical, moble ?
Horizontal or vertical ? What do you plan to use the antenna for ?

Hi John,

Visit:
http://bytemark.com/products/content2.htm
You will find background information here, but unfortunately they
don't maintain the pages very well and some information is lacking.

>How many do I need?

Depends on application. You want at least 3 times the expected load
Z. Ferrite Z is bulk determined and the usual standard of bulk size
is defined as a type 101 size bead.

>What permeability?

Type 43 or 64 material. 64 being slightly better (by about 15%).

>Who makes them capable of 450 MHz or so?

Amidon, but this is not proprietary (although the type specification
may be). There are other manufacturers like Fairite.

You must be talking about another Roy.

I have on several occasions contacted Roy and pointed out minor bugs
and every time I have been thanked for reporting the problem. Usually
a patch was forthcoming to me via email within a day if not sooner. A
public patch could be found on his web site shortly after.

I have to contrast this to a popular logging program that I use where
I have had similar difficulties and posted my comments on their
reflector. Once, the program developer had the nerve to call me on my
unlisted number and ask me to refrain from making such comments
because I was costing them sales. During that conversation I used Roy
as an example of how a software company *should* support its

customers.

They also have the MO of "saving up" bug fixes and selling me an annual "improved" program, something that I haven't had to do with EZNEC.

I don't believe that Amidon manufactures cores (except, apparently, custom ones through one if its subsidiaries), but only resells them. The last I checked, most of their ferrite cores are from Fair-Rite. The common numerical ferrite type designations of 43, 72, and so forth are Fair-Rite's.

They also sell powdered iron cores from Micrometals.

Hi Roy,

It is true that your program's user interface is not the best in
the world, but... Who cares? I think the free version of EZNEC
has made a lot for the ham community, much more than some of the
people criticizing you.

Best regards,

Maybe I gave you a trick answer, because the antenna I cited is a
receive-only device. It is concerned only with measuring the strength of the
electric field, and derives no phase information. I'm sure its efficiency is
horrible, but its bandwidth is huge and its gain is about +/- 0.5 dB.

FYI, here's an example of this style of antenna:
http://www.ets-lindgren.com/productpage.cfm?model=3301B&producttype=Antennas

Even if it did not face into an active pre-amplifier, it would still be a
poor emitter anywhere below a few MHz. Electrically short is something that
hasn't been finessed yet.

From: n1jpr@hotmail.com
Message-ID: <95a201e0.0409270334.54db7534@posting.google.com>
Source record: 89061

It was easy!

I just slammed a couple of 100 ohm 2W carbon film resistors in parallel on the output SO239 of a SWR meter, and powered it from a CB transceiver. Center contact by plugging crumpled, twisted leads into hole. Grounding with help of a tiewrap. Extremely low SWR. The 2x 2-watt resistors became quite hot at 3W RF carrier after 10 min. keydown (well... let's sat 3 min. "mike-PTT-kept-pressed-by-rubberband").

I made the T2FD 400 ohm resistor as 4 "squares" of 4 x 100 ohm resistors, soldered as a series of diamonds. Painted in high temperature engine black paint. Will go inside a generous ABS project box, weather sealed but with weephole. Will hang asymetrically, to point weephole down. Ball of crumpled alu foil should help keep bugs out, yet allow dripping.

Nominally, that would be 16x2=32W. Derated to 1/3 (say, 10W) should be still OK with up to 30W RF out @ 100% duty cycle, down to the minimum frequency.

It probably could take more at low duty cycle or higher frequencies, but I won't put in anything more, as the balun I made includes 60V neons between feedpoints and ground, to provide paranoid clipping of pulses from nearby lightning strikes.

If matching is fair, they'd clip at about 70W, as impedance referred to ground is 50 ohm. OK for QRP or for typical surplus 20W manpack operation.

Yes, of course. It's embarassing to misspell a noted author's name. My
apologies.

Hi, Ralph -

Yes, I can see that now. A little over two turns of RG58, tightly wound, on a .75 inch diameter is about right to be resonant around 440 MHz. However, the resonant frequency moves with compression and expansion of the coil (not unexpectedly) making it difficult to settle on the dimensions.

The problem here is that I must have no leads on the coil while experimenting because the leads affect the frequency. Later, when I create the coil at the base of the antenna, I will not be able to determine the coil's exact resonant frequency and adjust it for my frequency of operation.

I think I'll give up on this idea.

Thanks for your comments.

John

Thanks for the info, Richard.

Is there a way to add toroids to RG58 and measure the resulting
effectiveness? Maybe measure the RF on the shield with an RF Voltmeter?

Hi John,

Apply a steady, known power to a resistor (25 - 75 Ohms) and measure the voltage (more for sanity's sake). Add one core to the lead (make leads as short as possible, but long enough to allow ONE core to be added. Measure the drop across BOTH the resistor AND the core. Measure the drop across EACH, the resistor and the core. Across the core means at the wire passing through the center, as if the core were a leaded component with leads emerging from either side (it will NOT act like a short! - ain't science wunnerful?). Standard ratiometrics will reveal the core's Z.

You need only measure one core at a time, the addition of cores is additive just like series resistors. Unlike chained resistors, successive passes of the same wire through the core raises the Z by the square of the turns. A "turn" is defined as each passage of a conductor through the center (do not confuse with loops which may give rise to the appearance of a "turn" that in fact does not have a lead through the center; or that you lose a turn by counting only loops).

I've made coiled-coax choke baluns at 440MHz. Seems to work fine.
Generally expect to use pretty small line, to be able to make a small
enough coil. The self-resonance is nice but not critical. You're
just looking for a moderately high impedance. I have a program that
does a good job of estimating the self-resonant frequencies of coils,
but it's not on this machine so I can't check for you...I think one of
Reg Edward's programs also estimates self resonance for coils. If you
can get an impedance that's a few times the load impedance, you should
be OK. In feeding an antenna, it may be as important to use a couple
such chokes, spaced about a quarter wave apart, to keep the antenna
from coupling strongly to a possibly resonant section of feedline.

Cheers,
Tom

Hi,

I am running an 817 and I'd like to go out portabel with this rig.

I am planning to buy an Outbacker on a tripod, using a handmade metal mount with the possibility to attach a counterpoise.

Will the Outbacker work in this setup? Or does it need a lot of metal like cars habe?

I would use a counterpoise of course.

Any hints or suggestions?

Thanks for that info, Tom.

If resonance is not necessary, then I need only one turn of .75 diameter to make sure resonance is higher than my operating frequency. That would make the coil with parasitic capacitance look inductive.

A quarter wave vertical needs quarter wave radials at 90 degrees to the vertical.

A half wave vertical does not need radials as it is complete but needs fed at the center with the coax running out 90 degrees to the dipole (as far as possible)

For formulas see URL:

>Any hints or suggestions?

An Outbacker can probably be made to work in this way, but I don't think it will work _well_. One of the local ham-clubs I belong to recently had a presentation from a guy who has been trying to work portable with a rather similar setup (a multiband mobile vertical, on a tripod, with counterpoise wires, and an FT817) - he sums up his results as "I can hear them OK, but nobody can hear me."

An Outbacker's efficiency is only a few percent - there are a lot of losses inherent in its design. Some people have referred to antennas of this type as a "tuned, lossy counterpoise, connected to a large untuned radiator known as a `car body'".

Since you're going to be running only a few watts of power, I think the Outbacker's rather low radiation efficiency is going to be rather frustrating for you. An Outbacker mounted up high on a Ford Aerostar, and fed with 50 watts PEP, gives me "Good mobile signal" reports from across the Western U.S. on 40 meters... but fed with a few watts from an FT817, with only a minimal counterpoise located fairly close to the earth's surface, and I think you may have trouble being heard well.

For less weight and far less cost than an Outbacker plus tripod plus counterpoise, you could carry a "yo-yo" adjustable-length wire dipole plus coaxial feedline plus a Norcal BLT or similar lightweight tuner. String this up from a couple of convenient trees, and you'll get an order of magnitude more signal out - probably 1-2 S-units more.

For other options, see http://www.amqrp.org/projects/projects.html - take a look at the "Crappie Antenna" and the "St. Louis Vertical" - two interesting ways of using a very-lightweight collapsing fishing pole as an antenna support.

3760. DIY Omni TV receiver antenna challenge

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-27 19:58:05 UTC
From: angelo@oceansystems.com
Message-ID: <864d4e6b.0409271158.5b059f6b@posting.google.com>
Source record: 88981

I wish to hoist an antenna up a sailboat mast on a halyard to help receive TV stations when out in the Chesapeake Bay. The challenge is that the boat will rotate at anchor with the wind and even turn the antanna on it's axis as it it "hoisted" by rope and not locked rotationally.

There are commercially available antennas .. but it looks to me that it's simply a "fat" folded dipole. I would think that I could construct it's equivalent using the basic homemade folded dipole approach.

<http://www.boatenna.com/framesample1_000002.htm>

Any other suggestions for a do-it-yourself antenna? It's not often that I want to watch TV when on the boat (i.e. the reason I'm out there) so I was hoping to build something myself out of thick guage wire and 300ohm antenna wire.

Would 2 stacked folded dipoles with a 90deg offset (and "X") be an effective approach?

If I just do the loop, what would you recommend the diameter be for mid-range VHF5-13 or so?

Thanks in advance
Angelo

That would work - it's a "turnstile" configuration.

Another fairly common approach is to build a 300-ohm folded dipole,
and then bend the dipole into an "S" shape. This gives it a fairly
omnidirectional pattern, eliminating the null-off-the-end of a
straight dipole. You could probably build one of these out of
heavy-gauge copper or aluminum wire.

Hi Randy,

Religious fanaticism is anti liberty, and liberty
is the foundation of American values. To speak
out against this lunacy does not make one anti
religious, just anti fanatic... anti zealot - a
distinction that seems to have evaded you.

The Islamic Jihadist's and terrorists are religious
zealots (fanatics) that hate liberty loving folks
(liberals) every bit as much as you do. Zealots
are zealots, regardless of clothes they wear or
the deity they worship.

Jesus' sermon on the mound, was certainly NOT
about fanaticism... or political power, deception,
and spreading lies about opponents... just the
opposite, in fact!

That said, you should have noticed the topic
of my post was about political ramifications in
regards to ham radio. It was not anti-religious.

> doublet?

It depends! One big consideration is "on which band"?

On 80 meters, the 88 footer will do a better job than the 67 footer
because the feedpoint Z is higher and less reactive. If you can get to
132 feet, things get really good on 80 - but that's a lot of space to
find.

The 88 footer will theoretically have some gain broadside to the wire
on 40 through 20 meters because it's longer than a half wave but
shorter than a 1.28 wave (think of two 5/8 wave verticals back to
back..) Above 20 you theoretically get a cloverleaf pattern.

W4RNL explains it better than I can but you already know that...

> In either case, feedline would be approx. 50 ft. of 450 Ohm ladder
> line to a 4:1 current balun, then a short length of coax into the shack.

That's the rub - feeding the beast.

Model the thing with Reg Edwards' DIPOLE3 freeware and see what you
can expect on the various bands.

> My usual band of choice is 40, but I'd like to become more active on 20 and
> 30.

If you can get the feed figured out, it might be worth doing. Be aware
that the gain isn't more than a few dB, and an inefficient feed system
can eat a lot of it up.

Ideally, you'd eliminate the balun and run straight to a balanced
tuner. All depends on your house/shack situation. Some family members
take a dim view of new holes in new walls - can't understand why...

Hi Wes,

There is no doubt, Roy is an excellent
engineer, but as an interface programmer,
IMO, the opposite is true. Apparently, my
experience has not been the same as
yours, but in any case, there is no excuse
for inconsistency... or demeaning those
who request help on NGs as a result.

Um, actually it quite explicitly states it uses "Cool Cable." You
might try some Hip Cable as a substitute.

>>This antenna would be appealing because of the natural balun.

The "natural" of the BalUn is probably in the balance and the
orthogonal geometry.

>> However, they make no mention of the required coax velocity factor nor of
>> the terminal impedance.

Reckon on the outer surface velocity factor (it is really only a thick
radiator) which, if you are using solid coax is 1 (lower if it has
insulation).

>> I tried constructing one and measuring with a
>> vector voltmeter but the data were inconclusive. That is, I don't think I
>> know how to make measurements like this at 440 MHz yet. It is much
>> trickier than I thought.

Please share your data.

>>
>> In any case, can someone tell me:
>>
>> - Can RG58 be used, or will the velocity factor mess up the antenna?

already answered.

>> - What will be the terminal impedance?

Depends on dimension, folded dipoles multiply the load on the basis of
separation and ratios of thickness of each side of the fold (in this
case I presume it is identical - so the relation, if I recall
correctly will be roughly 4 fold for halfwave dimension or 300 Ohms).

I concentrate mostly on HF design, so someone will probably (now why
would I say probably?) correct any mistakes offered here.

>> - Will the terminal impedance change as the gap between the elements vary?

Only if it is a remarkably variation. Bench top precision in
construction at 440 MHz is not going to upset anything radically.

>> (I consider the "terminal" at the midpoint of the bottom element)

It is actually at the gap. The midpoint of the bottom element is
electrically neutral which makes mounting simpler.

Hmm, this seems to go against all the advice I've gotten so far, about getting as much of the antenna outside as possible...I find it hard to believe that an active antenna is going to get better reception than a 75' wire, but if it does, than it does...

Hi OM,

Not sure what you are responding to, but the implication you offer of
an active antenna surviving in a field of noise better than a remote
antenna is a sure cause of wonderment.

From their web site for 11 meter antennas:
"The STAR Antennas are high perfomance (spelled performance) long
distance ground wave antennas. They will do an excellent job in DX with
power - handling capabilities rated at 5 KW."

1. DX is not allowed on 11M.
2. 5KW is not allowed on 11M.
3. I will never buy a 10M antenna with the name "Hillbilly" in the title.

So, I'd say study real hard, get a Ham Radio license, build a dipole,
and get rid of the Mullet wearing/Bubba mentality.

"Now I saw in my dream that Christian and Hopeful forsook Mr. By-ends,
and kept their distance before him; but one of them looking back, saw
three men following Mr. By-ends, and behold, as they came up with him,
he made them a very low bow; and they also gave him a compliment. The
men's names were Mr. Hold-the-world, Mr. Money-love, and Mr. Save-all;
men that Mr. By-ends had formerly been acquainted with; for in their
minority they were schoolfellows, and were taught by one Mr.
Gripe-man, a schoolmaster in Love-gain, which is a market town in the
county of Coveting, in the north. This schoolmaster taught them the
art of getting, either by violence, cozenage, flattery, lying, or by
putting on the guise of religion; and these four gentlemen had
attained much of the art of their master, so that they could each of
them have kept such a school themselves.

"Well, when they had, as I said, thus saluted each other, Mr.
Money-love said to Mr. By-ends, Who are they upon the road before us?
(for Christian and Hopeful were yet within view).

"BY-ENDS. They are a couple of far countrymen, that, after their mode,
are going on pilgrimage.

"MONEY-LOVE. Alas! Why did they not stay, that we might have had
their good company? for they, and we, and you, Sir, I hope, are all
going on pilgrimage.

"BY-ENDS. Why, they, after their headstrong manner, conclude that it
is duty to rush on their journey all weathers; and I am for waiting
for wind and tide. They are for hazarding all for God at a clap; and
I am for taking all advantages to secure my life and estate. They are
for holding their notions, though all other men are against them; but
I am for religion in what, and so far as the times, and my safety,
will bear it. They are for religion when in rags and contempt; but I

am for him when he walks in his golden slippers, in the sunshine, and with applause."

The two bands are not quite harmonically related, so getting one
antenna to work for both will be tough.

You might look at a 5/8 wave antenna for two meters. It could be
within yelling distance of a 1/4 wave for somewhere on 6 meters.

2 antennas might fulfill your requirements-- The Larson 2 meter 5/8 wave,
mounted on a piece of pipe , aprox . 57-60 inches long, with a cap, and
BIGGER than the coax/connector your useing. (to make a "coaxial verticle)
or-- build a ground-plane, again, with the larson antenna (0r a whip
aproximately 55 inches long, but this time , use radials , in the horizontal
plane. works on 6 meters as 1/2 wave, 2 meters as a 5/8 wave, mounted against
a 1/4 wave (for counterpoise)! And, the 144 MHz works even better on six,
folks have found, than their 50 MHz verticle for mobile! easy to build,
especially the coaxial antenna, if you have a drillbit for the vertical -
just drill thru the cap! Jim NN7K

If you built a dipole, then it was (most likely) not a quarter-wave - but a half-wave
a j-pole may be a good choice given the situation that it needs to be 'out the window' and is uhf
or, for that matter, a coaxial half-wave dipole. (strip and fold back 1/4-wave of braid - and weatherproof it)

Peter -

I have been running the Outbacker "outreach" for almost 10 years for a 3rd floor patio .. have worked 100 countries (largely 20, 15, 10 with a bit on 17 and 40) ... I don't stay up late enough for 75 meters outside of the locals. I DO use the Alpha Delta OUTPOST- Tripod/ground coupler ground mount system (serves as a counterpoise) for use with the OUTREACH. http://www.alphadeltacom.com/pg5.htm

Next question?

> mounted wtith radials. Tks.

Of the ones I know about, I think the butternut HF2V is the best. And
they do make an add on kit for 160. The HF2V is a 40/80 vertical , and
is a full 1/4 wave on 40m. I think they also make a 30m kit if I
remember right...Also they have a top loading kit for the lower bands.
But you could do just as well with a 32 ft wire hung from a tree, and
a tapped coil at the base...For much less $$$$ too....The HF2V will
smoke the HF9V "the all band version" on the lower bands. MK

Hi Tom,

When common sense takes the back seat (or left to hitch-hike home),
fables have often risen in defense against the caprice of arbitrary
power. Literature is rich in regard to the travesty of logic that is
being passed off as the boon of a new age. I could have as easily
found material in the Canterbury Tales, The Decameron, The Song of
Roland, The Poem of the Cid.... The effete nabobs of negativism in
our Administration shrink in sharp contrast to the legendary heroes of
fighting cultures. Bush in his flight suit and helmet reminds me of
that pathetic picture of Dukakis in the Tank - what a matched pair!

Chuck,

If you check American History, you will see a lot of colonies were founded for religious freedom. As a Baptist, one of our unique features is an emphasis on religious liberty. We can agree to disagree, but true Chrisitanity seeks liberty. Also, many of our presidents were Christian or religious. Religious expression is found in our guiding documents, such as the Dec. of Independence, and the Constitution.

Islam is not the same as Christianity. Not all religions are the same or teach the same. Just remember that "theology" can be different, but ethics, such as the Golden Rule, can be the same.Look at the core beliefs and you will see major differences. One of the differences is that Islam practices conversion by the sword. Some misguided Christians in the past have also practiced it, but as you point out the Sermon on the Mount does not support it.

I am a Christian "fanatic" as it is my job and my passion. It has changed my life for the better. I vote my Christian beliefs, irregardless of the political party. And the Bible tells us to pray for the kings over us. Since we do not have a king, but we can see a principle to pray for our government leaders - All of them.

It is not lunacy to accept and practice religious belief (and I am talking in general terms of all the world religions and sects). What is lunacy is to misapply religion and use for personal gain, to control people or put people down because of differing beliefs (For more religious discrimination, check out Islam and Hinduism, and the Eastern Orthodox churches).

As you said, the foundation of American Values is liberty and that includes the free practice of religious beliefs.

BTW instead of WWJD, WRJU - What Radio would Jesus Use? With all of his travels, I would guess an FT-817 portable radio. :-)

Hi Chuck,

I didn't know that program, but I'll Google for it and have a look. In any case, from it's name, I infer that it is a Yagui design/optimize program that may be very good, but only for advanced amateurs.

What I was referring to, and this is what makes EZNEC special, is the posibility of "try and see". You read about, for ex., delta match and go to EZNEC and try it. You can experiment what happens if the match is too long or too short or... whatever. This is specially good to check that your design is not too critical. If you see that small differences in element construction will cause big degradation you can forget building it with real tools and materials.

As for the price, effectively, free isn't everything but it helps with programs whose utility is not clear until you have used them for long enough. I know this is the shareware concept but I reckon it does not work for business. Roy's intermediate approach seems good to me: reduced but sufficient functionality for the masses and full for whoever pays it.

Yep, and that expression is one of hope that the government not be beholden to any Official Christianity. For the past couple of millennia, Official Christianity has been seeking the divine path and simultaneously exterminating all those who would diverge from the Official Truth. Life has gotten very troublesome when several competing versions of Official Christian Truth have had to share the same time and space.

Christianity does not seek liberty, and in the historical record, has often been liberty's greatest foe. Of the various flavors of Christianity available today, broadly, to be a Christian, you have to either recognize a religious hierarchy as superior to your individual liberty, or accept the literal word of the Bible, which can only be done by Faith (which let's you ignore a whole lot of problematic Biblical advice).

The trouble with being a True Believer is that there is no way to agree to disagree. No matter how politely you disagree with my truth, that's heresy! How can I let a heretic teach my kids in public school? I must struggle (in the best jihad sense) to help the truth prevail. You must be persuaded, re-educated, or.... eliminated.

BTW, I think that only Rhode Island & Providence Plantations was formed mostly for religious freedom (fleeing the hobnailed boots of religious intolerance then existing in....., uhhh, Massachusetts), all the other American colonies were formed to turn a profit for an investment trust. And, a hundred years later, those God-fearing folks were up to their eyebrows in utilizing and turning a big profit from black slavery. Who woulda thunk it, Brown Sugar?

3796. 88 ft + 66 ft fanned doublet?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-28 11:35:33 UTC
From: Ken <cprstn54zz@att.net>
Message-ID: <3ciil0p72th5ikatrpvlifvt143mnfhu1u@4ax.com>
Source record: 89017

Will such a wire antenna give me good coverage of all HF ham bands 80M
and shorter?

According to Cebik in his article, ï¿½My Top Five Backyard Multi-Band
Wire HF antennas," an 88 ft doublet (or double zepp) is not so good
for 10, 12, 15 or 17M, whereas a 44 ft doublet is good on those
bands. See:
http://www.cebik.com/fdim/fdim9.pdf

Will a fanned doublet using 88 ft and 44 ft wires cover all the HF
bands, 80M and shorter? How about 88 ft and 33 ft?

If fanning works, is there a shorter wire that will give me 6, 10, 12,
15 and 17M?

I recently had a 44-ft doublet up, with 42 feet of 450 ohm line to a
coiled coax choke balun. With my tuner, it worked well from 30 thru
10, and required no tuner at all on 12. If you combined that with
something for 40 & 80, you'd be all set.

Suppose I construct the antenna as shown except put a Tee at the bottom for convenience. What will be the impedance at that point? After all, that would now be the feed point, yes?

3800. Tower / Antenna package for sale

Newsgroup: rec.radio.amateur.antenna
Date: 2004-09-28 14:14:04 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <Mke6d.213$kq6.105769@news4.srv.hcvlny.cv.net>
Source record: 88871

Tower / Antenna Package $1400

Pickup only - Location near Poughkeepsie, NY

Universal 40' tilt-over aluminum tower
Includes rotor shelf, bolts, leg stubs.
Installed 2 years. Now on ground.
Used with light load (the quad listed below).
Can haul in any light pickup truck.
You need to buy the legs that go into your concrete base.

Cubex 5-band Quad
20, 17, 15, 12 , 10 meters.
Separate feeds; includes coax stubs for all bands.
New (still in box) wire elements.
Extra boom (can be used as mast)
Fiberglass spreaders in exellent condition.

Amertron 5-way remote coax switch and control
Includes about 125' cable.
Needed for separate quad feeds.
Perfect condition.

Yaesu G450A rotator and control
Includes about 125' cable.
Excellent condition.
Perfect for quad.

All in excellent condition. You can inspect everything.

You need to add the coax feed, the legs that go into your
concrete base, and about 2 yards of concrete.

Replacement cost over $2600 + $$$ shipping.

Hi Richard, need we point out to you the absurdity of comparison between a pretender waving from armor he never saw before in his life, to a qualifed USAF jet fighter pilot who gets suited back up for a carrier landing? We can find a lot of things to disagree with President Bush's policies about, but one thing he is not, is a phony.

WolfMan wrote:
"And would there be an advantage with a 1/2-wave over a 1/4-wave?"

Short answer: Yes.

A dipole is directive. It has nulls at its ends and concentrates response perpendicular to the wire. Even a very short, almost vanishing dipole has these directional characteristics to some extent.

The theoretical isotropic antenna is the only truly nondirectional, gainless antenna. Directive gain is the power intensity that is radiated in the perferred direction versus the power intensity averaged in all directions (1955 Terman, page 871).

Directive gain of an elementary doublet (dipole) is 1.5 as compared with an isotropic. The gain of a resonant 1/2-wave is only 1.64, which is only some better than a very short elementary doublet.

Gain and directivity are only part of the antenna story. Radiation resistance and loss resistance appear as series components of a load resistance. The larger the radiation resistance is as compared with loss resistance, the more efficient is the antenna.

Radiation resistance of a short dipole is almost proportional to the square of its length. So, it rised rapidly as the antenna gets longer in terms of wavelength for the too short antenna. More radiation resistance is usually better because efficiency rises.

Kraus says in his 1950 edition on page 137 that a dipole of 0.1 wavelength has a radiation resistance of 7.9 ohms. If the dipole is only 0,01 wavelength, its radiation resistance is 0.08 ohms. This agrees with the length squared formula.

On page 146, Kraus says that the radiation resistance of an ordinary 1/2-wave dipole in free space is 73 ohms. This will be more efficient than an antenna about 1/2 the size in nearly all cases.

Best regards, Richard Harrison, KB5WZI

Yes, some have, and (already some time ago) one of them send me the
course manual to thank me for making 4nec2 available, so I was able to
check 4nec2 against the lessons included in the course.

Furthermore I somehow got a copy of all the example files in nec
format. For as far as I know (from my memory) all examples did work
without problems using 4nec2.

I am not quite sure, but maybe it's also possible to use the EZnec
demo which is for free. If you like it you can then still decide to
puchase the full EZnec version.

Success,
Arie.

Just forget everything that could be said about the antennas. the specs are laughable. Yes they are overpriced even if they were a decent antenna. Plans on how to build a good 10M beam are too abundant to waste money on this as you can build your own from scratch using only a small amount of extra effort.

The dipole Kraus is analyzing (shown in his fig. 5-1 on p. 127) isn't what we'd normally call an "ordinary dipole". As this figure and the accompanying text show, Kraus' short dipole is heavily end loaded to cause the current to be uniform along its length. This increases its radiation resistance by exactly a factor of four over that of a short unloaded dipole (a plain straight piece of wire fed in the center), whose current drops uniformly from the center to a value of zero at the ends.

The equation for a short unloaded dipole can be found in the same edition of Kraus on p. 262 as eq. 10-63, R11 = 5 * (beta * L)^2. The quantity in parentheses (beta * L) equals 2 * pi * the dipole length in wavelengths, so for a 0.1 wavelength dipole, it gives the radiation resistance as just a smidge under 2 ohms. (EZNEC gives just over 2 ohms for example model Dipole1.ez with the frequency changed to 60 MHz to make the antenna 0.1 wavelength long. Remember that the Kraus formula is an approximation, and for an infinitesimally thin antenna.)

This makes Richard's observation about efficiency even more true.

>

Peter,

As you probably know, you change bands on the Outbacker by changing the tap.
There are separate taps for 75 and 80 meters.

The 2:1 bandwidth (as expected) for 75 and 80 meter usage is only about 50
kHz.

For 40 meters it is better - about 150 to 175 kHz .. although with the Icom
756Pro antenna tuner I can improve this a bit more.

For the higher frequencies (20 through 10 meters), it covers the bands
fairly well, but I only use about 250 kHz on the 20 meter allocation.

Disadvantage is having to move the tap .. if you change bands.

Advantage, you can disassemble the antenna fairly quickly for portable usage
(or antenna restriction requirements)

wrote:

>We can
>find a lot of things to disagree with President Bush's policies about, but
>one thing he is not, is a phony.

Hi Jack,

Now there's a forced presumption. :-)

Then says Rollanz: "Wherefore so wroth with me?" He answers him:
"Comrade, it was your deed: Vassalage comes by sense, and not folly;
Prudence more worth is than stupidity. Here are Franks dead, all for
your trickery; No more service to Carlun may we yield. My lord were
here now, had you trusted me, And fought and won this battle then had
we, Taken or slain were the king Marsilie. In your prowess, Rollanz,
no good we've seen! Charles the great in vain your aid will seek --
None such as he till God His Judgement speak; -- Here must you die,
and France in shame be steeped; Here perishes our loyal company,
Before this night great severance and grief." AOI.

A pretty rough translation, no doubt about it, but from another:

"Then Roland says: 'Why are you angry with me?'
And he answers: 'Companion, it is your own doing, for knightly
courage used with prudence is one thing and folly is another, and
tempered judgment is more to be valued than the rashness of
arrogance. Those French are dead because of your heedlessness,
and we will never act again in Charles' service. If you had listened
to me, my lord would have returned and we would have won this
battle and King Marsiliun would have been captured or killed.
Woe to us, Roland, that we ever saw your bravery! Charles the
Great, a man whose like will never be see again until God judges
the world, will no longer be able to rely on our help, and you will
die, and shame will come to France. Today our faithful friendship
will end, and before evening we will have parted in sorrow."

<kd5yikes@mindspring.com> wrote:

>So, I should use 300 Ohm coax?

Hi John,

No such thing, or it would be quite expensive (amounting to no such
thing).

>Suppose I construct the antenna as shown except put a Tee at the bottom for
>convenience. What will be the impedance at that point? After all, that would
>now be the feed point, yes?

No. The feed point is at the inner conductor connection to the outer
conductor. The bend in the line (where you would put the tee) is
merely a bend in the line. You could choose any point in the line,
would that qualify it as a feed point? No. Your eye is merely drawn
to it through the magic of an illustration's symmetry. As a practical
matter, yes you could insert a tee there (provided you open one leg,
you see? even here we have to maintain the continuity out to the true
feed point).

I must add that my analysis on the Z transformation may be at fault.
Again, my focus is in larger antennas where these kind of machinations
would be prohibitive. Others should have chimed in by now, but they
seem transfixed with my postings on politics or bored altogether. It
seems to me that you already have the text description before you.
Certainly in a 800+ page tome Kraus isn't mute on the subject?

On the other hand, you have the instrumentation and the scale of
construction is not so demanding that you couldn't resolve this
yourself at the bench in an evening. We have too many dream weavers
here already and I have pleaded with them to perform simple tests that
apparently befuddle them. Imagine me posing the task of taking
several SWR measurements being responded to with 100 posting threads
of confusion as to how!

I would use solid coax simply because I have several hundred feet of
precision material. It was what we used for 900 MHz spread spectrum
so 400 MHz is no great shakes.

Roy, W7EL wrote:
"The dipole Kraus is analyzing (as shown in his fig. 5-1 on page 127) isn`t what we`d normally call an ordinary dipole."

Yes. Roy is right. On page 136, Kraus says:
"Let us now calculate the radiation resistance of the short dipole of Fig. 5-1."

The dipole of Fig. 5-1 has its ends loaded with capacitive hats. The result of the very short, in terms of wavelength, dipole and its capacitive loading are to cause the same current throughout the dipole. This is not the case in an ordinary dipole where current drops to near zero at its ends.

My mistake was searching for numbers that would give an idea of how radiation resistance varies as an antenna drops in length below resonant length, and not reading the whole chapter.

As Roy says, on page 262 Kraus writes: When the length L is small, (10-62) reduces very nearly to R11 = 5(beta L)squared ohms.

Best regards, Richard Harrison, KB5WZI

3811. The Problem of Mixing Religion and Science

The Thermodynamics of Hell

The following is an actual question given on a University of Washington chemistry mid-term. The answer by one student was so "profound" that the professor shared it with colleagues, via the internet which is, of course, why we now have the pleasure of enjoying it as well.

Bonus question: Is Hell exothermic (gives off heat)or endothermic (absorbs heat)?

Most of the students wrote proofs of their beliefs using Boyle's Law (gas cools when it expands and heats when it is compressed) or some variant. One student wrote the following:

"First, we need to know how the mass of Hell is changing in time. So we need to know the rate at which souls are moving into Hell and the rate at which they are leaving. I think that we can safely assume that once a soul gets to Hell, it will not leave. Therefore, no souls are leaving. As for how many souls are entering Hell, let's look at the different religions that exist in the world today. Most of these religions state that if you are not a member of their religion, you will go to Hell. Since there is more than one of these religions and since people do not belong to more than one religion, we can project that all souls go to Hell. With birth and death rates as they are, we can expect the number of souls in Hell to increase exponentially. Now, we look at the rate of change of the volume in Hell because Boyle's Law states that in order for the temperature and pressure in Hell to stay the same, the volume of Hell has to expand proportionately as souls are added.

This gives two possibilities:

1. If Hell is expanding at a slower rate than the rate at which souls enter Hell, then the temperature and pressure in Hell will increase until all Hell breaks loose.

2. If Hell is expanding at a rate faster than the increase of souls in Hell, then the temperature and pressure will drop until Hell freezes over.

So, which is it? If we accept the postulate given to me by Jan during my Freshman year that, " ... it will be a cold day in Hell before I sleep with you," and take into account the fact that I still have not succeeded in having an affair with her, then # 2 above cannot be true, and thus I am sure that Hell is exothermic and will not freeze over."

This student received the only "A."

****

NOTE, the entirety of the material above is not mine, but arrived by email anonymously and unrelated to matters discussed in this group.

My only comment is that this should be a candidate for Instant Classic.

A true believer you are, Jack...

Consider the fact that Bush did not complete
his pilot training by refusing to take his annual
flight physical and flight review, thus was
removed from flight status. Phoney docs aside,
his military record is good authority to verify this.
The fact that he claims to be a fighter pilot not
only makes the man a phony, he is a dishonest
one as well.

Oh... he was not a USAF officer, but a member
if the ANG - a USAF auxillary.

Neighborhood covenant was recently ammended to allow vertical antennas and to exclude beam antennas other than TV antennas and smaller. Fortunately for me my tribander was already grandfathered in, I lived here before it was a neighborhood.. I want to make the best of a Rhon 25 tower I have stored away. My tower is 50ft tall and could be extented even taller using vertical elements that did not support a load other than themselves. I was thinking of tuning the tower into a Giant copper Cactus antenna for 20M thru UHF by fastening 1/4 wl stubs on the side of the tower. Any reason why this would not work.

>
> As you said, the foundation of American Values is liberty and that includes the
> free practice of religious beliefs.

Indeed, which includess the liberty to not practice
a religion as well.

To consider Hinduism and Islam as similar, strongly
suggests a lack of understanding of either.

In regards to discrimination, one must understand
Hinduism believes in the law of Karma: "as ye sow
so shall ye reap". If one is born to a lowly state in
this life, it is a result of bad actions in a previous life,
thus one is deserving of their current state of
existence.

That said, I agree that true Christianity seeks liberty
(It is obvious that the Christ's teachings were liberal)
but the modern Christian Churches do not practice
true Christianity at all.

Allow me to elaborate:

Islam, Judaism, and modern Christianity all believe
in the god of Abraham. The Christ said he came to
"throw out the old law" - which can only be construed
as meaning the OT and the god of Abraham.

Christ's God is a God of love, compassion, brotherly
love, humility, judge not, and live and let live, etc...

In contrast, Abraham's god was violent, angry,
hateful, jealous, full of spite, and sought vengeance
by killing the unfaithful.

From this, it is easy to see why the world is so
violent and full of hate, given that the major religions
use such a horrific deity as an example for living
one's life.

From snopes.com -

The piece quoted above likely began as a humor post to the newsgroup rec.humor in 1997.
Its roots, however, are far older: an unattributed parody of a scientific proof concluding Heaven was
hotter than Hell appeared in a 1972 edition of Applied Optics, a story found in a 1962 book (reprinted
from a 1960 magazine) is a mathematical "proof" that heaven is hotter than hell, and article
published in a 1979 edition of the Journal of Irreproducible Results written by Dr. Tim Healey (written
as a response to the Applied Optics piece) carried the joke one step farther by arguing that Hell was
hotter still. Though these older pieces don't directly correlate with what has now become a
standardized bit of Internet lore, the themes are similar enough for us to postulate that the older
versions sparked the newer ones.

I think you misunderstand, but that is most likely because I have a hard time conveying what's in my mind. Especially in print and expecially at my age. I didn't used to have that problem...

I take a half-wave (at 1.0 velocity factor) length of RG58 with a BNC connector on one end and make a hairpin loop. This is the left side of the folded dipole. The BNC connector is at the bottom center. I take another half-wave piece of RG58 with a BNC connector connected to the shield only, and make a hairpin loop for the right side of the folded dipole. Now I install a T at the bottom between the left and right sides. As for the upper element, I attach the center wire of the left half to the shield of the right half. I repeat, the center conductor of the coax on the right side is not used.

Now I have an antenna completely constructed with a feedpoint at the bottom center via the T. What is the impedance at the T?

> I must add that my analysis on the Z transformation may be at fault.

Almost mute, yes. The only discussion for this particular arrangement is beneath the figure where it says "(a) A folded dipole has zero potential at

the midpoint of the lower dipole half at all frequencies. Thus, this point is ideal to attache a coaxial cable."

> On the other hand, you have the instrumentation and the scale of

> several SWR measurements being responded to with 100 posting threads
> of confusion as to how!

I recently got some of the instruments I now have. Owning them, however, does not mean I know what I'm doing with them. This is my first foray into UHF and the instruments and techniques are new to me. Yes, I can handle complex arithmetic, but that doesn't mean I know how to set up a test properly at 440 MHz.

Resolve this in an evening? I first have to learn how to make the measurements with some accuracy and repeatability before I can get meaningful results. At this frequency, I've learned, even getting a true short circuit takes care.

Also, I have nobody to work with me as I try all this new stuff. This group is the only resource I have with people who are knowledgeable enough to answer such questions.

I'm doing the best I can.

73,
John

Hal,

Your idea using the J-Pole is probabaly the best solution.
1. No radials needed
2. Easy to match using ANY type of feedline
3. Total length is about 3/4 wavelength (about 52") including matching
section
4. Easy to contruct

We found this URL that may give you an idea regarding contruction.

As someone who has done a large amount of software design and implementation with highly varied target audiences, I would suggest that making the design such that minimal need for reference to the manual because of multiple paths to user desired results is something to be looked at seriously. Sorry about the awkward verbage, I'm not sure how to express it elegantly.

Tom, you're absolutely right. And the number of times I've been asked this particular question shows that I do need to address the issue being discussed.

But. . .

While there are some standards which can just about universally be agreed on as far as usability and consistency are concerned, there are vast differences in opionion about how a large number of features should be handled. An interface that's intuitive to one person is hopelessly awkward to another. I know this for a fact, since I get comments clear across the spectrum about the program and its interface. During product development, I often ask the beta testers to choose among two or more ways of implementing a feature, and seldom get unanimity. Two things I've learned in this very interesting endeavor are: 1. Avoid making changes or implementing features to please one or a small number of people. 2. You can't please everyone. Considering the complexity of the program, it's a certainty that everyone can find something he doesn't like.

Complaints like Chuck's would bother me if it weren't for the very large number of positive comments I receive, the amateurs and professional customers who continue to purchase upgrades, and the commercial customers who keep buying more and more copies. Complaints and negative comments aren't to be ignored by any means, but the positive feedback keeps them in context. Anyone who does buy the program gets a fast and complete refund if not fully satisfied (although, ironically, they might not know that if they're unwilling to open the manual) -- there's simply no way to get a bad deal and no excuse to feel cheated. The demo program is exactly like the full program with the single exception of the segment limit, and includes the full manual, so anyone can see exactly what the program is like before they buy it. Those who don't like it hopefully won't buy it.

It is indeed my goal to make the program operable without any reference to the manual. A secondary goal is to make the manual as complete as possible, so a user can easily find out how to do something that isn't immediately obvious (remembering that what's obvious to one person is often obtuse to another). I'll never fully meet both goals, but I do keep trying. And I appreciate the suggestions and comments.

Chuck,

Reread my post. I said that Islam and Hinduism both practice religious discrimination. In fact Islam is monthiestic will Hindi's are polytheistic.

As you posted, religious liberty includes the right not to practice. But religious liberty also includes my right to vote based on religious beliefs, to work as a minister seeking to help mankind, and even evangelise and pass out information in public forums.

Of the 13 colonies that were founded for religious freedom, I can think of Mass., Rhode Island, New Jersey, Pennsylvania, and Maryland. 5 out of 13. Several other colonies offered freedom from religious discrimination.

This is as it should be - for a folded halfwave dipole. However,
there is some question that this is intention of the design expressed
with great paucity of facts by Kraus. More on this below.

>Now I have an antenna completely constructed with a feedpoint at the bottom
>center via the T. What is the impedance at the T?

It will be the transform of that load found at the opposite side where
the signal is developed by the connection of the inner conductor to
the outer shield. More on this below.

>Almost mute, yes. The only discussion for this particular arrangement is
>beneath the figure where it says "(a) A folded dipole has zero potential at

More useful is it can be attached to a metal support without
interfering.

You need to add a directional coupler to separate out the forward and
reverse components is all.

Do you have a manual? I've been trying to find a link to HP manuals
that was offered in this group in the last couple of months. The "App
Notes" written during the 60s offer a complete education without
requiring a double-E to understand.

>Also, I have nobody to work with me as I try all this new stuff. This group

> works enough, but I know I can do better...

I had a noise problem with a longwire. I got a 4:1 balun from LDG, it's meant to be used with their autotuners, bit also can be used by itself.

On the high impedance side of the balun, one side goes to the antenna, and the other side to ground. You then use coax to connect to your receiver. I mounted the balun on the wall right where the antenna leaves the house, and connected the ground terminal to a ground rod directly below that point.

The reduction in noise was dramatic! This tells me that what you propose should work for you, as long as you can connect one side of the high-impedance side to a good ground. In a dorm room, I don't know if you have a decent RF ground available, depends on the circumstances of the plumbing, etc.

If the balun is not too expensive, it is probably worth your while to get one and to experiment. Try yo buy one from a place with a liberal return policy, in case it does not work for you.

Good luck!

>More on this below.

It seems in my effort to find the page(s) associated with HP and your equipment, I forgot to expand on the issues promised.

The antenna is generally known as a "shielded, balanced dipole." This is often applied to receive applications. For the dimensions you suggest (halfwave overall length), the Z multiplication would indeed present a 6:1 mismatch - on average.

To answer your question about what Z would be present at the "feed point": it would fall along the circumference of a constant SWR 6:1 circle (speaking of a Smith Chart solution) depending upon the length of the electrical distance to the true feed point. This will be greater than the halfwave of the antenna structure given that its electrical length is not confounded by insulation properties.

I have seen this design used for repeaters, but in a 4 bay configuration. Undoubtedly the harness feeding it was composed of halfwave sections placed in parallel to draw down the mismatch (at least it acted like this, the wiring was hidden within the greater supporting structure).

Massachusetts was hardly "founded for religious freedom." It was founded by true believers who had The Answer. Escaping persecution doesn't mean one won't practice it when in power.

A strong case can be made that Hinduism is basically monotheistic -- as with many/most religions (Rabbinical Judaism and Islam excepted) the popular beliefs tend toward polytheism (e.g., Christian trinity, saints and he semi-deification of Mary).

While "work as a minister seeking to help mankind" might not be technically oxymoronic it is not more meaningful than "work as a garbage collector (or even, gasp, an EE) to help mankind."

Stay away from the coaxial dipoles. They are junk. The vynil used on the
ouside of coax is unsuitabe for use as the dielectric of an antenna element.
While there are good ways of making this antenna the 'strip the coax and
fold back the sheild' method is not one of them.

It may depend on the antenna. If they are made correctly longer antennas
will have more gain. If not made correctly they may not have any more gain
and may have less.

??? A single turn 3/4" diameter won't give you much reactance at 440.
Looks to me like if you used about three turns with that ID with a
total length around 1.5 inches, you'd be a lot better off. That'll be
about 300 ohms inductive reactance, shunted by enough parasitic
capacitance to come close to resonance (thus a higher net reactance).

Cheers,
Tom

>approximately 50 feet away from the house. I would like to get a
>decent lower band antenna (not 160). I'm wondering what would be the
>best scenario:

Hi Terry, My suggestion would be extend the tower as high as possible, and hang a 135' inverted vee, fed with open wire line. Of course you will have to use an antenna tuner and balun at the shack, but this antenna will work will work really well on your bands of interest. This would be a "best all around" antenna.
If your interest is solely dx, then a vertical or inverted "L" with lots of radials should be the way to go. The radials are a pain, compared to the ease of the vee mentioned above.

gain is had by reducing gain in other directions. There is nothing to
guarantee that using a gain antenna will cause an improvement;
the opposite may happen. Especially if the antenna is tilted.

Actually, Tom, my GDO measures about 440 with two tight turns. Add a couple of inches for leads and it goes lower. So, I figured I needed something slightly higher in resonance to be sure it is on the inductive side of 440.

No?

John

Well, actually, the Hundu religion is
monotheistic as well: many sub-deities, but
only one God.

Modern Christianity has many sub-deities
as well, only they are called angels.

The Hundu God is a loving god, as that of
the Christ, not warlike like the god of
Abraham which faux-Christians worship
today.

In any case, I took issue with your notion
of discrimination... perhaps you should
re-read my post.

>
> As you posted, religious liberty includes the right not to practice. But
> religious liberty also includes my right to vote based on religious beliefs, to

> information in public forums.

Yes, you can vote any way you wish, but if
your church holds a non-profit status, then
passing out political fliers is illegal, since this
makes your church a political orginization,
subject to taxation.

You do not have a right to be a criminal,
nor is it ethical (or honest) to usurp the
intent or spirit of that law.

If you really want to help mankind, then
mind your own business (worry about
'saving' yourself, not others) since
historically, religion has been responsible
for most wars, oppression, and human
misery!

>
> Of the 13 colonies that were founded for religious freedom, I can think of
> Mass., Rhode Island, New Jersey, Pennsylvania, and Maryland. 5 out of 13.
> Several other colonies offered freedom from religious discrimination.
>

Folks left Europe for the 'New World' mainly
to get away religious oppression - similar to
what we can expect from perverted cults like
your power hungry Pat Robertson's coalition.
You can Justify your actions by any number
of historical revisions, but the fact remains;
America was founded as a secular nation and
religion has no role to play in its government.

Now, if a bunch of crazy Mullah's were to take
your position - wishing to influence government
policy - your position would take a 180° turn in
NY minute... flip-flop!

Yes,G.B. should be kicked in the butt in declaring war when they were so
broke.
If the jews were not willing to react to Germany then the British should
have stayed put
just like the U.S. as there were no allies at the time, the British were
alone!
If things had happened that way then there would have no been reason
to have an Israel. If there was not an Israel the World would still be
united and the U.N.
would not be torn apart by the U.S. vetoes.
Parts of the World also would not have created a war
against Islam and thousands would still be alive.
If there was no war in Europe maybe the U.S. would have asked for help
against the
' pre emptive' attack, a type of attack that is now the norm.
Richard you have provided good food for thought, something like 'if a nail
was not lost
then a shoe would not have been lost ! '
Obviously the Britts were dummies in fighting those wars
, especially when Israel then turned on the U.K. and other countries
on a killing spree at home and abroard.....Yes it is all Britain's
fault

Not sure if the U.S. would have entered the war
if it wasn't for Japan but if G.B. told the Jewish bankers where to stick
their 40 pieces of silver

we would not now be at war against Islam and parts of the World where Islam is accepted and we
all would have been much happier .
O if we all had the benefit of hindsight the World would be a more peaceful place.

Hi all,

Thanks for all the replies that shows how to make a small antenna. I had no intention to start a political war in this mailing group. I was just thinking, if my brother was here, I wan't be asking simple question like this in a forum. However, the bottom line is WAR is no good! irrespective of who started it. 90% of the time, its the third party who suffers the most.

Message-ID: <saps22-qvc.ln1@p400bob.lse.com.au>
Source record: 88927

This actually begs another question.

How efficient compared to (say) a 1/2 wave dopole is the average cell phone antenna? I'd also like to know the difference between those handsets that have a antenna sticking out better or worse (dB pls) than those that dont.

I guess body attenuation wd be a major factor too.

Cheers Bob

Source record: 88926

Chuck, et al:

Yes, Jesus created the laws of physics and created the universe. I can hear it now, Creation vs Intellegent Design vs Evolution. 3 seperate ideas.. That is a Off Topic and Off List question.

How can you say Hinduism is a peaceful monotheistic religion? One of the major goddess is Shiva. Or what about Krishnia? They have hundreds of gods and goddess. In may parts of India, it is illegal to convert from Hinduism to another religion, often punished by torture and/or death. The Caste system and the Law of Karma is one of the major discriminators in the world.

The trinity is 1 God in three persons. As a Baptist, we do not diefy Mary the mother of Jesus nor worship the "Saints". The God of Abraham in the OT is the same God of the NT. God the father, God the Son (Jesus) and the Holy Spirit is one God in 3 essences. Sort of like a man being a husband, father and brother - three distinct roles, but one person. Angels are created beings, not to be worshipped or diefied as a God. May I suggest you read some of the historic creeds and confessions of faith, such as the Apostle Creed, Nicine Creed, The London Confession, and the Southern Baptist Statement of faith? This will help you better understand the main doctrines of Christianity verses some of the strange teachings seen on Trinity.

On the political side, when people ask or talk politics to me, I tell them that the Bible tells us to pray for the kings over us. Since USA does not have a king, the principle to be applied is pray for our Government leaders, starting with our local leaders, and pray for Kerry and Bush, or Bush and Kerry. The Bible also tells us to be good citizens, so please go vote. As you can see, I endorse no candiate or party. Even though position papers and voter guides (if they do not endorse any person or party) are legal to give out, I will not, because politics is too sensitive.

If asked a question, say for example, What does the Bible say about abortion, or any other issue, I will show what the Bible says. Basically, I say, read the Bible, read pro and con arguements and then make up your mind.

Christians should not be brain dead robots, but people with critical thinking skills. Of course, a Christian worldview should be based around the Bible. Yes. I have 2 degrees, and have studied most ot the world religions, science, philosophy and "humanism". I made my decision.

On money. If, I was after money, I would have stayed a mid-level computer programmer making 4 times my pastor salary. Would you be interested in donating a Raibeam to a poor preacher?? :-) But then I would need a tower and a rotor and approval from the Historical Commission...:-)

I did not know Trinity Broadcasting was being audited. I have heard about the sex scandal - One of the founders tried to bribe somebody not to talk of homosexual affair. Trinity is not on the local cable system, and I have strong concerns about them. Thanks for the info. In the past, I have watched Trinity mainly to see what strange clothes would be worn, and what outlandish statements made. Sure was fun, but sad -- thinking about the people being duped by them.

It is evident that you are well versed in the many world religions. May I suggest you read the series of books by Lee Strobel? They all start out "The Case for ..." Lee was a news reporter and atheist and has written several books detailing his experiences. Have you read Josh Mcdowells books on Evidences for Christianity? The Caner (Canar, sp?) brothers have some excellent books detailing how they grew up as Muslims and then converted to Christianity.

I'm confused by the statement that Juduism is not monothiestic. The Shema (Deuteronomy 6:4-9) clearly states that. Can you explain that?

It has been fun talking with you. It is past midnight. Time to go QRT.

Randy

3857. Re: NEWS - Researchers invent antenna for light

Newsgroup: rec.radio.amateur.antenna

Source record: 88928

(Inventor) Bob's (W1XYZ) patents on this form a basis for ownership on such varieties of antennas, within the construct of the claims. That is my opinion.

The fact that later academic groups allegedly claim discovery or invention on this or other new technologies is irrelevant: the assignee of he patent is what's important.

It is common for academic groups to be 5-20 years behind the state of the art in antenna work BTW.

The CNN story is a nice corroboration of Bob's innovation and invention, in my opinion. Of course, it wouldn't hurt to give the man some well-deserved credit. Again, this is also a fairly common problem in some academic groups these days, unfortunately.

Hat's off, Bob.

73,
Chip N1IR

Hi Jimmie,

the only problem i can forsee is that copper and Glavinized steep will
setup electrolisis which will corrode the connection. so you'll have to
treat for that problem.. other than that should work ok.

Hello,

To celebrate the 4th birthday of my site, I propose you a riddle : who am I ?
Four years ago was born a multidisciplinary French-speaking educational web site which dared to approach very original topics like the theory of relativity, quantum physics or the philosophy of sciences. In complement the autor being impassioned for astronomy, meteorologist, photographer and computist, he reserved a large part of his site to astrophysics, bioastronomy and amateur astrophotography, and did recently a digression to meteorology and ecology.
Eclectic in his opinions, prolific and verbose, wanting to touch even more readers, he opened new English pages devoted to amateur astronomy (astronomical optics, image processing, technical comments, software review), radioastronomy and amateur radio, as many activities that he practices with assiduity. But where does he find all this time wondered readers ?...
Today this site acquired its maturity and does propose you not less than 1200 educational pages, more than 7000 images and hundreds of animations and audio files. It even includes a translation module. It becames a reference as testify his guest book. Childs 12 years old connect to it as well as professors at university. One connects to it from all over the world, and to be accurate from 155 different countries. 40% of readers are English-speaking whose 12% come from the USA (6% from Can., 3% from the U.K., 1% from VK) ! To wonder what magnetism comes out from this site !...
But you will judge by yourself. Have you recognized it ?

Indeed, it's LUXORION, already 4 years ; -)

Source record: 88931

Terry, I have both vertical (shunt fed tower) and horizontal (loops, dipoles) antennas for 40, 80, and 160 -- and find that the dipoles work better for the local QSOs and the verticals work better for DX. Do whatever you can to get the tower as high as possible. My son had an old CB 102" mobile whip that I strapped to the top of this tower to make it 8 feet longer.

Shunt-feeding the tower is pretty straight-forward. It's a lot easier to accomplish with an antenna analyzer (I use an MFJ 259) but you can do it with just an SWR meter.

I would refer you to ON4UN's book, "Low Band DXing" -- great reference material.

Art Unwin wrote:
"Oh, if we all had the benefit of hindsight the world would be a more peaceful place."

Yes. We make guesses about results from our actions.

I wrote a response to Reg`s lament that Americans are armed and dangerous. Reg implied that Americans are responsible for messes in "ex-Yugoslavia, Iraq, Palestine, Afghanistan, and numerous other places in this small world."

Nations, including the U.S.A. must pursue their perceived self-interests. At times perceptions are wrong.

Oil fuels the world. It is every nation`s self-interest to ensure its energy supply.

Iraq had little to do with 9-11-1. Iraq was rewarding families of suicidal terrorists in Israel. Iraq had tried to assassinate the elder Bush, and Rumsfeld seized an opportunity to strike a blow for israel.

W. Bush told the U.S. Congress, Iraq won`t let the U.N. Arms Inspectors do their jobs. Empower me, the president, to enforce the U.N. Resolutions if Iraq doesn`t comply. It`s the only way to resolve the threat.

The U.S. Congress, eager to blame Bush and avoid responsibility itself for unwise decisions, "bravely" passed the resolution to allow Bush to go to war without its formal declaration of war. Congress thought highly of the Bush administration. Congress has a Republican majority and the Bush administration consisted of very experienced politicians. It was thought that the administration would make wise, if unpopular, choices.

It seems arrogance brought us to the current conditions. When you have allies, you must share control as well as responsibilities, and the U.S.A. thought it knew enough, was powerful enough, and rich enough not to really need much help in Iraq.

The truth is that Iraq was not just an Israeli or American problem and should have been handled with a world-wide coalition. The U.S. and Britain invaded only half-cocked.

Best regards, Richard Harrison, KB5WZI

Impedance value is 50ohms when matched. I don't know the current value, but
it would depend on the power.

snip.

Not so !!

Nations must pursue the perceived interests of the whole WORLD,
that is why the U.N. was set up. But then the U.S. nullified its intent
by excluding Israel from fault in anyway shape or form.
Until the U.S. declares what its intensions are with Israel the World
is on hold. The World perceives that the next World war or the biggest
threat
is Israel but the U.S. renders that Country as untouchable no matter what
even tho
they broke every condition ,all of them, accepted for the formation of
Israel.
Thus the U.N. is totally split regarding its function while the U.S.
retaines its
arrogance to those in the rest of the World.
When the U.S. begins its next pre-emptive attack against Islam they will
find out for themselves what it is really like to be on one's own.
When WW2 ended displacement camps were gradually emptied,
in the Mid East DP camps are getting larger every day despite helicopter
missile attacks every day, and now the U.S. has supplied the bunker buster
bombs to Israel that it needs for a pre emptive attack on Iran while the
U.S.
holds the World at bay.
If the U.K position in the big wars is to be knocked and had declined the
threat
wrapped up in the Balfour treaty until it had the support of the rest of the
World
then the U.S. is to be knocked for envisaging the Middle East in the same

way
we did in America,.kill all the occupants , take their lands and justify it
by
calling them heathens! We said that' they can run but they cannot hide'
how wrong we are to think that winning a Military war means an occupation of
peace

Hi Brian,

It's like your C5+ website. This is like I always knew it ;-)
I see also that in a few years to extended the web a lot.

"Ony 4" maybe means that it affected you more than expected, hi !
That looks positive.
I only regret to not be able to write better in English and provide you more
useful information.
So currently I only rely on the amateur radio section written in English
where I have developed what i think are interesting pages about ionosphere
and perturbations (solar and geomagnetic) without to speak about the other
subjects. Of course there are always some English page dealing with
technical reviews (optics, astro or radio/DSP software, etc), and
radioastronomy.
FYI, for all pages written in French there is always the translation module
that could help a little and that connect you to wordlingo (but you can also
use (altavista babelfish). The result is not too bad. ;-)

Source record: 88938
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

I have been searching the catalogs for an 18nanohenry inductor to use in conjunction with a Radiotronix RCR-433-RP Receiver and transmitter pair for a remote control I am working on. Radiotronix has an app note that shows this inductor used with a couple of 8.2pf caps to get good reception/transmission for their modules.

I have been unable to find a source other than surface mount parts. Does anyone know of a source for this size inductor, or know the formula that I would use to wind my own?

I am posting this to rec.radio.amateur.homebrew and rec.radio.amateur.antenna

TIA,

Joe

Ummm... this means the universe is
only about 2000 years old, right?

> How can you say Hinduism is a peaceful monotheistic religion? One of the major
> goddess is Shiva. Or what about Krishnia?

Shiva is a lower deity like an archangel...

Krishna was a man.

Most Hindi are vegetarians because they
do not believe in killing... that's peaceful.

Obviously, your mind is made up that
Hindu is not monotheistic.

> The Caste system and
> the Law of Karma is one of the major discriminators in the world.

The Law of Karma is similar to a law of
physics: for every action there is an
opposite and equal reaction - which can
also be said as: "as ye sow, so shall ye
reap".

I don't defend the cast system, but
I do understand its religious basis.

Let me suggest that you should inform
yourself in this regard as well.

> The God of Abraham in the OT is the
> same God of the NT.

Perhaps in the mind of faux-Christians...

But in reality they are contradictory: one a
god of love and compassion, the other a
god of hatred, violence, and oppression.

> On the political side, when people ask or talk politics to me, I tell them that
> the Bible tells us to pray for the kings over us.

The Bible also says to slay the wicked
and perform other violent acts - in complete
contradiction to the teachings of the Christ.

He said in regards to evangelism: "cast not
your pearls before swine".

In regards to politics: "leave unto Caesar
what is Caesar's... ".

The Bible is the work of man.

If you don't believe in abortion, then by all
means, do not have one. On the other hand,
what right have you to enforce your beliefs
on others?

>

Where is the critical thinking in ignoring
contradictions and believing illogical
silliness?

>Of course, a Christian worldview should be based around the Bible. Yes.

> philosophy and "humanism". I made my decision

Judging from what you write, either you
weren't paying much attention, or your
'course' was so biased towards the
evangelical point of view, that any
modicum of truth about 'world religions'
was, on the most part, lost.

>
> It is evident that you are well versed in the many world religions. May I
> suggest you read [...]

Been there, done than - many years ago.

Perhaps you should read the 'holy' books
of all religions on your own (as opposed
to being taught erroneous opinions). At
minimum, you could then hold a valid view.

>
> I'm confused by the statement that Juduism is not monothiestic.

So am I. I did not say that!

> It has been fun talking with you. It is past midnight. Time to go QRT.
>
> Randy

I'm glad you're having fun. In truth, this
seems more an excursive in futility, than
any thing else.

Though I was raised as a conservative
Christian, I am neither Hindu, Sikh, Muslim,
Buddhist, Jewish, Christian, Bahai', Mormon,
Eckancar, Brotherhood of light, etc,.

I do recognize there is a measure of truth in
them all (some more than others). For this
reason, it is salient that we do not suppress
any religious thought, or promote one over
another. America, like India, must remain
both democratic and secular.

Cheers,

Chuck, WA7RAI

Cell phone is -2 to -10 dB average down from 1/2 wave and the pattern is
very splintered.
The antenna resonates with parts inside the case and users arm.
Longer antenna is defiantly better, IF it is resonate.
If you get aftermarket, it may not be.
Has to be designed for that particular cellphone.

Yes. That`s pretty much the way it is. Remember the "Axis of Evil"? Bush named N. Korea and Iran as members, too. The U.S. has its hands full. Bush admits no mistakes, but Iraq and Iran only differ in spelling by one letter. Bush now knows it was Iran, not Iraq that should have been vanquished. Darn that misspelling! What to do? Give the weapons to Israel so thet can do the job on Irani nuclear facilities.

Best regards, Richard Harrison, KB5WZI

"Wind" ?

As a rule of thumb, a thin wire has an inductance about 1 nH/mm, so a
straight wire about 18 mm long would have the required inductance. For
a thicker wire, about 25-30 mm straight wire would be required. Even a
single turn would increase the inductance quickly, so you would have
to shorten the wire considerably.

If 18 nH surface mount inductors exists, why not use them ? At least
the inductance would be much predictable.

A one inch length of #18 AWG wire is about 18 nH at VHF and above, according to the ARRL Handbook, 2004 edition, page 10.10. The equation is:

L = .00508b[ln(2b/a)-.75] where

L is in uH
b is length in inches
a is wire radius in inches
and change the .75 to 1 for VHF and above

So, it kind of makes sense why they don't sell lead-mounted 18 nH inductors. People would complain that they only got one lead, and it's a short lead at that.

If I were trying it, I'd try a one-turn loop of about 1/4 diameter with leads just long enough to solder into the circuit. Maybe all you need is a kinky piece of wire and adjust the kink to tune.

Good luck,
John (KD5YI)

Does it crash, Reg? ;-)
Seriously, would it not be better to use a spiral PCB trace?
